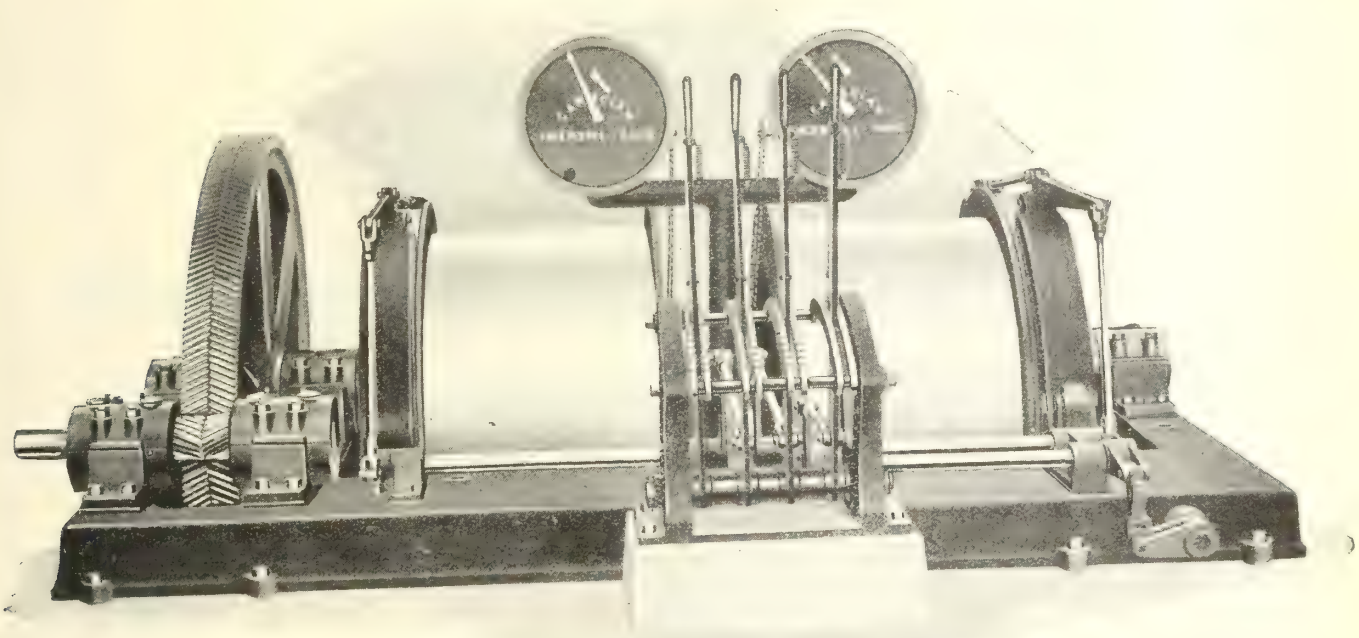
"CIRCO" HOISTS



Class "PE 1" Electric Hoist--with Gear Casing Removed.

Correct Design and Good Service Go Together

In "CIRCO" Hoists are found many features of advanced design and construction which add to their capacity, reliability and ease of operation.

Take the Class "PE-I" Double Drum, Single Reduction Helical Geared Electric Hoist shown above; the design provides for a low centre of gravity which reduces vibration and due to the short heavy-duty bearings and open type frame, with consequent low drum position, the need for an elevated platform is generally only necessary on the largest sizes.

This Hoist is rugged, compact and self-contained, requires a simple foundation and is easily erected in close quarters, thus it can often be installed in places where hoists of other design would be out of the question.

Clutches are of the band type, drum and pinion shafts are unusually heavy and well supported. The post brakes are balanced to permit easy operation. The double helical steel gears are accurately cut and well protected by oil pan and cover.

When desired these hoists can be equipped with rolled steel plate drum shells, air operated brakes, full magnetic control; automatic safety devices, etc.

Write for bulletins or consult our nearest branch regarding your requirements.

Analyses of Canadian Fuels. Part I to V, by E. Stansfield, M. Sc., and J. H. H. Nicolls, M. Sc.

Graphite, by H. S. Spence.

Gas Producer Trials with Alberta Coals, by J. Blizard and E. S. Malloch.

The Mines Branch maintains the following laboratories in which investigations are made with a view to assisting in the developing of the general mining industry of Canada:—

Fuel Testing Laboratory.—Testing value of Canadian fuels for steam raising and production of power gas; analyses, and other chemical and physical examinations of solid, liquid and gaseous fuels are also made.

Ore-Dressing Laboratory.—Testing of Canadian ores and minerals, to ascertain most economical methods of treatment.

Chemical Laboratory — Analyzing and assaying of all mineral substances and their manufactured products. Copies of schedules of fees, which are slightly in excess of those charged by private practitioners, may be had on application.

Ceramic Laboratory.—Equipment is such that complete physical tests on clays and shales of the Dominion can be made, to determine their value from an economic standpoint.

Structural Materials Laboratory.—Experimental work on sands, cements and limes is also undertaken.

Applications for reports and particulars relative to having investigations made in the several laboratories should be addressed to The Director, Mines Branch, Department of Mines, Ottawa.

Applicants for publications not listed above should mention the precise area concerning which information is desired.

Summary Report — The annual Summary Report of the Geological Survey is now printed in parts. Applicants should, therefore, state what particular geologist's report is required, or what subject they are interested in.

The Geological Survey will, under certain limitations, give information and advice upon subjects relating to general and economic geology. Mineral and rock specimens, when accompanied by definite statements of localities, will be examined and their nature reported upon.

Communications should be addressed to The Director, Geological Survey, Ottawa.

CANADIAN NATIONAL RAILWAYS

The Problem of Canadian Development

◆◆◆◆◆◆

The Industrial and Resources Department is engaged in developing Canadian industries and commercial opportunities.

INTELLIGENCE SERVICE

The department has a wide range of information on Canada's Natural Resources available to the public and invites enquiries of all kinds: Minerals, Forest Products, Agricultural Opportunities, Waterpowers.

Send for pamphlet "Minerals and Mining Industries on the Canadian National Railways."

Uniform Flotation Oils

Hercules Pine Oils for flotation are manufactured under the most complete chemical control that can be achieved by a trained and experienced organization, operating thoroughly modern plants.

The grade of Hercules Pine Oil which best meets your requirements having been determined, you may rest assured that every shipment will conform to the original specifications.

We desire to co-operate to the utmost with flotation operators in selecting the oils best suited to their needs and in supplying such oils regularly under proper specifications.

Write for booklet No. 200 which gives specifications for our standard grades.

Ontario's Minerals

PROVINCE OF ONTARIO

Hon. CHARLES. McCREA, Minister. DEPARTMENT OF MINES *Thos. W. Gibson*

Mineral Areas

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favourable for the occurrence of minerals 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver veins of Cobalt, Gowganda and South Lorrain occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

Economic Minerals

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario: — actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluorspar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, Portland cement, brick and tile, meet every demand.

Mineral Production

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1922 to be worth $62,202,169, of which the metallic production was $38,190,711.

The following figures show the growth of Ontario's mineral industry by five-year periods since 1891 when a Bureau of Mines was first established.

Year.	Value.	Year.	Value.
1891	$4,705,672	1911	$41,976,797
1896	5,235,003	1916	65,303,822
1901	11,831,086	1918 (Maximum war output)	80,308,972
1906	22,388,383	1921	48,128,387
	Dividends.		

Dividends and bonuses paid to the end of 1922 amounted to $28,096,699 for gold mining companies, and $86,238,185 for silver mining companies or a total of $114,334,884.

Mining Regulations

A miner's license costs $5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of $2.50 or $3.00 per acre, depending on location in unsurveyed or surveyed territory.

Assay Office

The Provincial Assays Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

Publications

For list of publications, illustrated reports, geological maps and mining laws, apply to

Thos. W. Gibson,
Deputy Minister of Mines.
TORONTO, CANADA

PROVINCE OF QUEBEC

MINES BRANCH

Department of Colonization, Mines and Fisheries

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, etc.

MINISTER OF COLONIZATION, MINES AND FISHERIES, QUEBEC

MINER'S CERTIFICATES. First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. The price of this certificate is $10 and is valid until the first of January following. This certificate gives the right to prospect on public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres.

WORKING CONDITIONS. During the first six months following the staking of the claim, work on it must be performed to the extent of at least twenty-five days of eight hours.

SIX MONTHS AFTER STAKING. At the expiration of six months from the date of the staking, the prospector, to retain his rights, must take out a mining license.

MINING LICENSE. The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cents an acre per year, and a fee of $10.00 on issue. It is valid for one year and is renewable on the same terms, on producing an affidavit that during the year work has been performed to the extent of at least twenty-five days' labour on each forty acres.

MINING CONCESSION. Notwithstanding the above, a mining concession may be acquired at any time at the rate of $5 an acre for SUPERIOR METALS, and $3 an acre for INFERIOR MINERALS.

The attention of prospectors is especially called to the territory in the North-Western part of the Province of Quebec north of the height of land, where important mineralized belts are known to exist.

PROVINCIAL LABORATORY. Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY, 228 ST. DENIS STREET, Montreal, for the determination, assays and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensure results of undoubted integrity and reliability.

The bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of the Province, on application addressed to

HONORABLE J. E. PERRAULT,

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

BRITISH COLUMBIA

The Mineral Province of Western Canada

Has produced Minerals valued as follows Placer Gold, $76,542,203; Lode Gold, $109,647,661; Silver, $59,814,266; Lead, $51,810,891; Copper, $170,723,242; Zinc, $24,625,839; Coal and Coke, $238,289,565; Building Stone, Brick Cement, etc., $36,605,942; Miscellaneous Minerals, $1,358,839; Making its mineral production to the end of 1922 show an

Aggregate Value of $734,259,619

The substantial progress of the Mining Industry of this Province is strikingly exhibited in the following figures, which show the value of production for successive five-year periods: For all years to 1895, inclusive $94,547,241; for five years, 1896-1900, $57,605,967; for five years, 1901-1905, $96,509,968; for five years, 1906-1910, $125,534,474; for five years, 1911-1915, $142,072,603; for 5 years 1915-1920, $189,922,725; 1921, $28,066,641; for the year 1922, $35,158,843.

Production During last ten years, $339,280,940

Lode-mining has only been in progress for about twenty-five years, and not 20 per cent. of the Province has been even prospected; 300,000 square miles of unexplored mineral bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than those of any other Province in the Dominion, or any Colony in the British Empire.

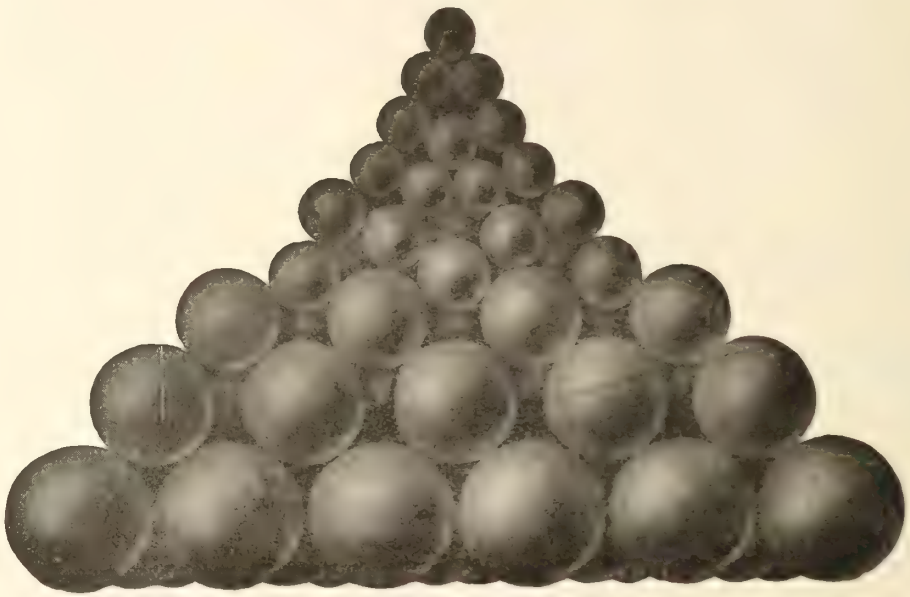
Mineral locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full information, together with Mining Reports and Maps, may be obtained gratis by addressing.

VICTORIA, British Columbia,
THE HON. THE MINISTER OF MINES.

Decrease your grinding costs.



USE HISCO BALLS

"If quality counts use 'Hisco' Products" *Hisco Balls* are noted for superior quality. They are in use in the largest ore and cement mills from Halifax to Vancouver. Forged from Electric Furnace chrome steel, absolutely the best ball on the market.

Sizes 3, 4, 5 and 6 inch carried in stock.
Special sizes from 6 inch up made to order.

Accompanying The Mining Engineer

The Imperial Bank is particularly adapted to the needs of the mining engineer. Wherever he may go in the Dominion this Bank accompanies him.

Every branch of this Bank — and there are 192 throughout the Dominion — is fully equipped to render an adequate banking service. The managers of our branches in the mining areas, because of their intimate knowledge of local conditions, can impart valuable information to those engaged in the mining industry.

You will never be far from your bank account if you deposit your funds with the Imperial Bank.

CANADIAN AGENTS

Jones & Glassco, Regd.

MONTREAL, TORONTO.

O.W. Ludwig, *Plant Superintendent of the Raymond Lead Co., Chicago, says:*

"Thirteen years of service without a repair is our experience with two 100 H.P and ten 20 H.P. Morse Silent Chain Drives

"When we moved into our present plant thirteen years ago, we installed the present Morse equipment of silent chains for our two lead mills and ten hydraulic pumps. We had always previously used leather belts, but not without considerable trouble. For instance, if the operator was not careful — and gave the motors too great a load, the leather belt would slip and in some cases burn out. While with the Morse Chain Drive we overload them at times up to 15 H.P. without the slightest trouble.

"When we used leather belts on the hydraulic pumps, if a pump packing suddenly gave way, the water would squirt all over the pump as well as adjoining pumps, causing the leather belts to get wet. This often necessitated a shut-down on 3 to 4 pumps to dry out each belt, thus causing a loss of time by the men, which resulted many times in paying overtime to catch up on the work. Of course, with our Morse Chain Drive we have no such trouble—this positive drive prevents slippage and is not affected by water.

"Leather belts lasted us 2 to 3 years at the most, while our Morse Chain Drives have already lasted 3 to 4 times that long and seem good for many more years. So Morse Drives have cut our expense materially, speeded up production, cut out overtime wages and saved floor space, for they operate on shorter centers."

NEW RAILWAYS FOR THE MINES

Of the very few pieces of railway construction under way in Canada at present, those in northeastern Ontario and northwestern Quebec are probably of most interest to mining men. Construction of the Larder Lake branch eastward from Swastika is well under way, and the Kipawa extension of the C. P. R. to des Quinze is nearing completion.

The extension from Kipawa to the water storage dam on des Quinze river where it flows from des Quinze lake is 68 miles long. At present the end of steel is within a few miles of the dam, and the construction engineers expect to have it at the dam by October first. The grade is almost completed throughout. There is a four-mile spur line from St. Placide to Ville-Marie, the county town, on Lake Temiskaming, the seat of the local mining recorder's office.

While the railway, at its present terminus at des Quinze dam, is pointed in the direction of the gold belt to the north, it is at a distance of 45 miles, and there is no assurance whatever as yet that it will be carried through. It is interesting to note that only the long-continued urgency of the community of 17,000 settlers round about Ville-Marie has brought the railway through to them. Even then, the Provincial Government has had to grant the C. P. R. a substantial cash bonus per mile and a concession of agricultural land of much greater potential value, to induce them to put their road through the 35 miles of difficult and barren land from Kipawa northward. The remaining 33 miles is through good farming land, which would attract any railway.

The interesting point to the mining fraternity is whether this Kipawa extension will be pushed northward. It can be said with certainty that no mines, alone, will induce this. We must remember that a single set of rails will outlive the average mine. Settlement is the great inducement to railway building; the farms will last forever. But mining will induce immediate settlement, so that it will require the conjunction of payable gold deposits and good farming land to draw the C. P. R. northward from the Quinze. The good land is there in abundance, but the mines have still to be proved.

Piquancy is added to the situation by the fact that the branch eastward along the gold belt from Swastika to Larder Lake will be within 17 miles of Lake Fortune before the year is out, and by the additional fact that it is being built under a federal charter. Will the T. & N. O. Railway Commission get to the prospective Quebec gold mines first, and draw the traffic down their line towards Toronto? This makes interesting speculation.

THE VALUE OF CONFIDENCE

In an inspiring address to the Canadian Club in Vancouver on Sept. 2th, Sir Edward Grigg outlined the probable direction in which the Imperial Economic Conference would be guided.

The keynote of Sir Edward's remarks was that the ways and means of arriving at economic provisions must be subordinated to the definition and acceptance of fundamental principles. Constitutional machinery may become ineffective and the assumption of obligations for the future enforcement of a stated policy may prove to be unacceptable when the time comes for its exercise, and may in fact impair the freedom of action that a changed situation demands. Thus principle rather than expediency must be the keynote of the Conference.

The genius of British foreign policy was described as being embodied in the principle of avoiding definite commitments to any single power or group of powers and dealing with each situation as it arises. Such a policy, if considered alone, might be described as pure opportunism, and it was forcefully pointed out that its vindication as well as its power lay in the firm adherence to an ideal purpose.

The purpose of British foreign policy to-day is the attainment of peace and settlement, and every situation that arises is dealt with in its relation to this purpose. The best work that the Imperial Economic Conference can do, the most efficient way in which it may seek to benefit the economic conditions of the Empire, is by setting itself to establish relations in accord with the ultimate requirements of peace and settlement, rather than by the formulation of arbitrary measures or creation of machinery that a future generation may repudiate.

The basic provision of the Treaty of Versailles, which called for the joint action of the United States and the British Empire in support of France, should she be attacked again by Germany, already repudiated by one party and disallowed by the other, is startling evidence of the futility of attempting to impose definite obligations in respect of indefinite or hypothetical situations.

There is a moral in all this of very pertinent applica-

tion to the mining industry of Canada. As peace and settlement are the dominant objectives of world-policies to-day, so confidence and reciprocity of thought are the essential requirements for the well-being of Canada's mining industry. To what end? — To the end that capital may be interested, — capital to investigate, to open up, to make liquid our mineral assets.

Just as economic stability is to be sought in the train of peace, so will an atmosphere of confidence do more to attract the investor than the most strenuous efforts for publicity for the mining industry.

It is the duty of everyone who is genuinely interested in the advancement of the mining industry (and this we deem our especial privilege) to do his utmost to inspire confidence, and that can be done only by a frank presentation of all pertinent facts and an open discussion of the whole matter, not forgetting the point of view of the man outside the industry.

GOOD ROADS WITH POOR SURFACES

At this season of the year it is the custom of our road builders to commence sizing up the result of their year's effort. The "good roads" movement is having a very satisfactory result, in all but one respect; many of the good roads are poor roads.

We have drawn attention on numerous occasions to the fact that, almost without exception, soft rock of inferior wearing quality is used to surface our roads—even our "good" roads — wherever it is available. We have seen more than one instance of roads surfaced mile after mile with limestone rock, when good, hard trap rock was available in the immediate locality. It does not seem to strike our builders of roads that it is an excellent investment to use the trap rock. Though it may cost a trifle more to quarry, crush and roll the harder rock, its useful life is anywhere from three to ten times as long.

Surely this is not stupidity or mere "cussedness" on the part of our builders of roads; it must be due either to the force of habit or to ignorance. Let us give them the benefit of the doubt, and say that they are wasting vast sums annually in putting down shoddy macadam, a fast-wearing concrete aggregate, and an inferior filler with their asphalt because they do not realize the facts of the case. "Penny wise and pound foolish" is costing the country millions annually in soft road surfaces.

How can this waste be prevented? — Very simply; by using good rock wherever it is economically available. Fortunately, good road material is fairly well distributed throughout eastern Canada, where the principal road-building investment now is in progress. The Mines Branch, Ottawa, has examined and reported upon the road-building materials of a large part of these eastern provinces. Unfortunately, these reports do not emphasize sufficiently the superior value of hard rocks such as trap over even the best of limestones.

We have a suggestion to make, which may be of practical utility. The Mines Branch has a fund of useful information on road-building materials, and has the facilities for gathering more as required. Its officers can demonstrate in numerous ways the economy of using good rock for surfacing our permanent roadways. Let our practical road builders and their business executives consult these technical officers, and among them they will work out ways and means of lessening the present appalling annual waste due to shoddy surfaces.

THE LAST OF A DISGRACEFUL EPISODE

Last winter the Labrador stock-jobbing campaign was preceded by preparatory paragraphs in the daily papers, making the public ready for the flaring advertisements that were to follow. Immediately these paragraphs appeared, the *Canadian Mining Journal* got in touch with a well-known mining engineer in Newfoundland, and on the basis of the information he supplied exposed the whole infamous project. Recently we asked this same authority for the facts as determined during the past summer, and he has replied as follows:

"While I did not go to Labrador myself, I have interviewed all the returned prospectors, with the result that there is no question that the whole thing was one of the most bare-faced swindles in my experience of mining.

"The original discovery by Bellew was a fake.

"The reported discovery by the Stanley May party was due to the salting of the samples taken. The opinion of Captain Jeffreys is that the salting was done after the samples reached Montreal.

"Mr. Casson, who accompanied the Jeffreys party this summer, coming from California to do so, stated that in his opinion there was not a colour of gold within fifty miles of Big Brook, Stag Bay, where the supposed discoveries were located. Mr. Wilson of Timmins said the same, as did also Captain Thomson of Liverpool, England.

"Captain Jeffreys is firmly convinced there is no alluvial gold on the Labrador. Fred Chalmers, who is a prospector of many years experience and who took a party from St. John's, made the same statement.

"Furthermore, all these men stated that the formation was all glacial on the coast for many miles and consisted entirely of detritus from granite; that the reported black sand was ground-up hornblende; that for thirty miles back from the coast no other formation but granite was encountered. All these men were very indignant over the whole thing.

"In my opinion, responsibility for the hoax rests primarily upon Bellew, who unquestionably lied. In the second place it rests upon the Stanley May party, who, in spite of having an experienced engineer with

them, allowed their samples to be salted. I believe no blame attaches to Mr. May, who was convinced that gold was there, probably in paying quantities. In the third place, the Newfoundland government should be severely censured for not sending a competent man to investigate the alleged discovery as soon as it was reported."

This engineer in Newfoundland has done a public service in keeping the *Canadian Mining Journal* posted as to some of the facts of this disgraceful episode. It does not seem likely that the culprits will be prosecuted or made to repay the sums got from the public on false pretences. At this point we shall write finis to the affair.

A SILVER PROSPECT IN QUEBEC

While the present productive area of the South Lorrain silver camp is confined to the hundred acres or so in which the Keeley and Frontier ore-shoots have been developed, further underground prospecting now under way promises to extend the field. Active development is in hand on some of the adjoining properties, and at least one outlying property, the Maidens, two and one-half miles to the northeast near the shore of Lake Temiskaming, is to be investigated thoroughly.

The evidence upon which the Maidens property is deemed worthy of investigation is cited by Mr. C. W. Knight in his recent report on South Lorrain. It consists, in brief, of the presence of well-defined and wide calcite veins containing smaltite and occasional low values in silver, occurring in rock of Kewatin age. This rock is underlaid by the same sill of diabase that appears at the Keeley and Frontier. The contact of the two rocks has not been explored where cut by the veins. It is hoped to find ore-shoots there.

There is a case that appears to be somewhat similar, and likewise worth investigation, six miles to the east, across Lake Temiskaming in Quebec. In Fabre parish, one and one-half miles east of the hamlet of Fabre and four miles east of Fabre wharf, there were discovered in 1906 two or three veins of smaltite in Keewatin greenstone, which is underlaid by a sill of Nipissing diabase. These veins are up to two inches in width, and show a little silver on assay. In 1907 a shaft was sunk on one of these veins for a distance of 50 to 75 feet. At this point the Keewatin rock is probably 100 to 125 feet thick over the sill, so the shaft probably was sunk about half way to the contact.

This old prospect has been idle since 1907. The Kipawa extension of the Canadian Pacific Railway now runs within less than three quarters of a mile east of the property. It could be explored cheaply. Will the present interest and activity in South Lorrain spread eastward across the lake into Quebec?

EMPIRE MINING AND METALLURGICAL CONGRESS TO BE HELD AT THE BRITISH EMPIRE EXHIBITION, 1924

His Royal Highness the Prince of Wales has consented to become Honorary President of the forthcoming Empire Mining and Metallurgical Congress.

The following institutions are co-operating as convenors of the Congress which will be held at the British Empire Exhibition in London during the first week in June, 1924:—

The Institution of Mining and Metallurgy,
The Institution of Mining Engineers,
The Institution of Petroleum Technologists,
The Iron and Steel Institute and,
The Institute of Metals,

representing the Scientific and Technical interests of the Mineral and Metal Industries, with

The Mining Association of Great Britain and
The National Federation of Iron and Steel Manufacturers, representing the Colliery Proprietors and Iron and Steel Manufacturers respectively, of the British Isles.

This is the first Empire Mining and Metallurgical Congress to be held and it is anticipated that succeeding sessions will be held in the Dominions under the auspices of an Empire Council of Mining and Metallurgical Engineering Institutions, which it is hoped will be constituted as a result of the inaugural Congress.

Viscount Long of Wraxall (late Secretary of State for the Colonies) has accepted the invitation of The Institution of Mining and Metallurgy to deliver the "Sir Julius Wernher Memorial Lecture" at the opening Session of the Congress, and he will take as his subject Mineral Resources and their relation to the prosperity and development of the Empire. The "May Lecture" of the Institute of Metals to be delivered by Dr. F. W. Aston, F.R.S., will also form part of the programme of the Congress. Dr. Aston's subject will be "Atoms and Isotopes".

CORPORATIONS THAT BELIEVE IN RESEARCH

Twenty large manufacturing corporations in the United States, whose names appear below, maintain extensive Industrial Laboratories. Why? Because it pays.

American Rolling Mill Company.
American Brass Company.
Detroit Edison Company.
Dodge Brothers.
Du Pont de Nemours and Company.
Eastman Kodak Company.
General Electric Company.
General Motors Company.
The B. F. Goodrich Company.
International Acheson Graphite Company.
National Carbon Company.
National Cash Register Company.
National Electric Lamp Association.
New Jersey Zinc Company.
Pennsylvania Railroad Company.
Reo Motor Company.
Studebaker Corporation.
T. A. Edison Laboratories.
Westinghouse Electric and Manufacturing Company.
Western Electric Company.

We have similarly enlightened corporations in Canada, but not enough of them.

The Pas Mineral Belt in 1923

Report to the Commissioner of Northern Manitoba

By R. C. WALLACE

In the mineral belt north of The Pas as a whole, there has been a comparatively quiet period since the operations of last summer. The most important progress has been at Herb Lake, where the Bingo interests are pursuing a programme of underground development with very satisfactory results. Further work at Herb Lake, both in gold and silver-lead, very promising development work in gold at Elbow Lake, and further operations in diamond-drilling and intensive prospecting by the Flin Flon interests, with some other work in the copper belt, constitute the major operations of the season. Although the work done has been rather limited, in several areas it calls for special attention, owing to its significance for mining interests who are keeping in close touch with developments in this field.

The operations in this district may be grouped under three headings: (1) copper, (2) gold, and (3) silver-lead. In a general way, this represents also the order of mineralisation from west to east in the belt.

Copper

Copper prices and the copper market have not been strong in recent months, and work in the copper area has been affected accordingly. The Flin Flon interests are continuing diamond drilling operations, and are at present working southeast of the main ore-body. They have also a fairly large party under Dr. Armstrong carrying out a programme of intensive prospecting in the district.

In the main, prospectors are confining their attention to the Northeast Arm of Athapapuskow lake, in the vicinity of Sourdough Bay, where the indications appear to be the most favorable for the discovery of further copper ore-bodies.

Little has been done on the Baker-Patton group since last summer, when considerable surface trenching was done by the London Exploration Company. The property can best be explored by diamond-drilling, and at relatively small cost. Towards the south end of the Neo claim, and at the north end of the Zero claim, shallow holes across the muskeg would give valuable information on this property, which is now held under option. Somewhat east of the strike of the porphry schist on this group, very good copper ore appears as float on the east side of an island on Thompson Lake (Don Juan claim), apparently almost in place, under the lake surface. This will be trenched when the water level lowers in late summer.

To the west of the Baker-Patton group, on the Rosen claims and adjoining properties to the south, in a sheared greenstone west of Stewart lake, considerable mineralisation with chalcopyrite occurs, in places showing good values. When prospecting for copper ore-bodies becomes general, the west shore of Stewart lake will be diamond-drilled, as one of the likely areas in this district. On the east side of the Northeast Arm, a substantial body of iron sulphide occurs, with a showing of copper on the Fox claim. Little work has been done in this zone of mineralisation.

The showings on the Northeast Arm indicate that both in the quartz porphyry and in the associated greenstone, mineralisation with sulphides of iron and copper is general in several parallel zones. The edges of the lakes, the muskegs and low-lying clay-covered areas in these zones, where copper is fairly abundant in the adjacent higher ground, are good prospecting ground by diamond-drill for copper ore-bodies.

Gold

Bingo — Underground work is proceeding at the Bingo mine, on the east side of Herb Lake. The shaft had reached a depth of 225 feet at the beginning of August, and sinking was to be continued to 400 feet. Approximately 310 feet of drifting has been done on the 200-foot level north and south of the shaft, and a cross-cut has been run (50 feet) from the north drift, and another (80 feet) from the south drift, crosscutting on both sides of the drift. The underground work to date shows the vein on which the shaft was sunk, and the parallel vein to the east, continuing downwards in very well-marked fissures. On both walls in each vein considerable movement has taken place, with good promise of continuing in depth. The quartz shows more volume than at the surface, with considerable widening between the 50-foot and 100-foot depths, and carries a good deal of galena with the pyrite. The country rock, which dips with the veins approximately 75 degrees east, is a sheared fine-grained acidic lava, well shattered on the footwall, and cut by numerous stringers of quartz. In the free gold showings in the vein-stuff, as for instance below the 200-foot level, the gold appears to be associated mainly with the galena but is very clean and is presumably almost completely free-milling. The equipment installed for development purposes is complete, and work is proceeding rapidly and efficiently, and at low cost. A staff of 25 men is employed, working in three shifts, and the sinking is being carried on by contract. Altogether, developments are of a very encouraging nature on this property, and bid fair to assist in a material way the whole Herb Lake camp.

Murray — On the Murray property, at the south end of Elbow Lake, on which considerable surface work was done by the Hollinger interests last year before relinquishing their option, further work has now been done in following the high-grade showings in the low-dipping veins or sheets cutting the altered contact complex which forms the mineralised country rock on the property. Underground work will be necessary in order to determine the structure with accuracy; but the sheets appear to dip to the northwest with an average angle of 35 degrees, with occasional folds and reverse dips, the quartz filling later cross-fractures in a vertically dipping country rock. Two sheets have been followed by deep trenching which shows unusually heavy free gold on the footwall practically throughout the workings. The shaft has been sunk to 42 feet, and the shattered country rock at the bottom of the shaft carried values in gold. Development work on the property will doubtless be concentrated on the quartz sheets, and the continuation of the tunnel to crosscut the sheets will be of considerable assistance in planning a development pro-

gramme on the property. The present surface showings and values justify a programme of development, not aimed at large-scale operations on the quartz and country rock, but confined to the quartz sheets on which recent surface work has been done. The property is fully equipped with buildings which have been well cared for by the present management.

Elbow Lake — In the Elbow Lake area are several so-called "porphyry dykes"—parallel zones of shearing in a porphyry schist, impregnated with veins and stringers of quartz, and in many instances carrying a considerable proportion of iron carbonate. On account of their width and continuity, these zones are attractive, and a good deal of work has been done on several of them. Unfortunately they have hitherto showed from cross-channeled samples too low values in gold for successful operation in this district. On the Garbutt zone, one of the strongest in the district, Webb has now uncovered a shoot that may have important significance. On the quartz stringers across the zone, and with some lateral continuity, there are abundant free gold showings associated with galena. From a 2-foot widening of one of the quartz veinlets in particular, a very fine ore has been cobbed for treatment. There is not yet enough work done to determine the extent of the shoot; but it is of importance in indicating that at least one shoot occurs in this type of zone, and that the chances are reasonably favorable for other shoots being found on careful prospecting. What is needed here, and on other zones similar to the Garbutt, such as the Shamrock group, the Point showings, and the Bank group, is that companies be given the opportunity, and be obligated, to do extensive work on their options without any considerable payments to owners for a sufficient length of time to permit of such zones as the Garbutt to be thoroughly prospected. On that basis good companies will be attracted, and real progress will be made.

As an illustration of the value of careful surface prospecting, there has been uncovered in the northeast end of the Herb Lake area on property that had been staked and re-staked without any work being done (the Byng claim) a fairly strong vein of quartz running across the strike of the porphyry schist, and fissured like the quartz of the Rex vein. Prospecting of this kind is needed on many properties that have now been held for some time, as the statutory assessment work is too often of very little value in prospecting the property.

Lead-Silver

A galena-silver mineralisation occurs in the sediments on the north end of Herb Lake, and a considerable amount of development work has been done on the outcrop north of the Little Herb river by Paul Gasse for American interests. The rock is an almost flat-bedded quartzite, underlaid by a soft mica schist, and flanked on the west by a coarse pegmatite, which has intruded the sediments. The work on the shaft and crosscut shows that the silver-bearing galena is confined to the quartzite, which extends to a depth of 17 feet at the shaft. The galena occurs in bands in the sediments, the main band striking 20 degrees east of north. The most northerly trench in this zone shows very heavy mineralisation with galena over a width of 20 feet. The ore seems to increase in width and value towards the north, and there is good prospecting country in the clay-covered country north of the north trench. The silver averages $1.30 to every unit percent of lead. Massive sphalerite has been uncovered immediately east of the main galena mineralisation, though apparently not associated with the galena.

Rumors of a native silver discovery somewhere between the mineral belt and the Churchill river have resulted in several parties going northwards through Kississing lake to the Churchill river and Grenville lake. To date the explorations have been unsuccessful in the search for silver. A large iron sulphide body was discovered in the Kississing lakes, on which some sampling has been done. Under present conditions of transportation it is obvious that only high-grade ore-bodies of large size would be of any economic value in territory so far removed from the main avenues of transportation.

Summary

Both at Herb Lake and Elbow Lake the outlook is decidedly encouraging for the development of gold properties. The underground results on the Bingo at Herb Lake, and the surface discoveries on the Murray and Garbutt properties at Elbow Lake, will attract the attention of responsible mining companies to both districts. With renewed activity, it is hoped that owners will feel their responsibility in prospecting their properties, and seeing to it that the assessment work is done to good advantage to themselves and the whole district.

The world copper situation has affected progress in the copper area, but there are indications that underground prospecting will continue, particularly in the Northeast Arm of Athapapuskow lake. To judge from surface showings, the chances for ore-bodies being discovered in that area are good.

Work is proceeding rapidly to determine whether the galena-silver occurrence in the sediments on the Little Herb river is sufficiently extensive to grade as an ore-body. Much work will yet be required before the extent of the mineralisation in a heavily clay-covered country can be fully estimated.

PERSONAL AND GENERAL

An indication of the wide-spread effect of a prosperous mining industry is the recent appointment of Mr. N. A. Timmins, President of Hollinger Consolidated, to the board of directors of the Riordon pulp and paper company.

Mr. E. L. Marthelem has been appointed electrical engineer for the coal mining operations centered round Glace Bay, Nova Scotia.

Dr. J. A. L. Henderson of London, consulting engineer to the Anglo-French Exploration Company, is in Canada in the Company's interest.

During recent years an additional and substantial amount of petroleum has been won from abandoned fields in France and Belgium by underground mining methods. When the petroleum-bearing strata are not too deeply buried, it has been found profitable to sink shafts and from there to run drifts into the strata, into which the oil percolates. Dr. Charles Camsell, Deputy Minister of Mines, will examine these fields before he returns from Europe, with a view to gauging the applicability of this method to the shallow oil-fields of southwestern Ontario.

Canada's developed resources are said to be worth from eighteen to twenty-five billion dollars. In ten years of systematic scientific experiment, we believe they would be worth one hundred billion dollars.

Some Thoughts about Currency

By H. G. NICHOLS

Considering the practical importance of the subject of currency to the man in the street, it is remarkable to note how few people have any very clear idea of the problems connected with it, and the diversity of opinions expressed by those who have thought about it most affords some excuse for venturing upon the discussion. That the question of currency is one of particular interest to the mining fraternity is evidenced by the discussion recently initiated by the Institution of Mining and Metallurgy in London, and carried on by the English technical press. It is perhaps a pity that this discussion was restricted to the consideration of the re-valuation of gold, for that, after all, is only one suggested means to an end.

Throughout many centuries, it has always been the question of how individual interests are to be related to one another that has given rise to the complexities of the currency problem. In the latter part of the last century the conception of the necessity for some form of universal medium had been reached, and found expression in the proposition laid before the Paris conference of 1878, that "the use of both gold and silver as unlimited legal tender may be safely adopted; first by equalizing them at a relation to be fixed by international agreement, etc." But the time was not yet ripe for the acceptance of the universal or international application of a fixed ratio. It has required the events of recent years to establish the common cause of humanity as a fundamental principle in business relations. And it is because the common good as the motive force in world-policies today is before the nations that we may again approach this subject with an open mind, considering it as a matter of first principles and divested of the incubus of former dialectics. This is not an easy matter; even the simplest-sounding axiomatic definitions are liable to go astray, from force of habit.

What is "Value?"

The very first point to be studied is in connection with the abstract idea of value. Take three commodities, wheat, iron and coal, and suppose they are being used for the sole purpose of ballasting a ship; then their interchangeability would depend upon their weight, and it would not matter whether their weights were gauged in poods, pounds or kilos, they would have to balance up against so many cubic feet of water. Weight is an abstract idea, then, that is not explained by the symbols employed, but only expressed by them, and these symbols would be useless unless they were invariably true to the central idea of weight. The use of our three commodities then is as weights; their interchangeability is determined by a common requirement.

Let us call the weight of a cubic foot of water .. .. w

and the weight of a cubic foot of wheat .. .. $\frac{w}{a}$

and the weight of a cubic foot of iron .. .. $\frac{w}{b}$

and the weight of a cubic foot of coal .. .. $\frac{w}{c}$

One may be changed for the other in the ratio, a : b : c; but the extent to which any of them may be used for our purpose depends upon the constant w, and you can take so many poods, pounds or kilos of wheat, iron or coal, knowing that you are dealing in equivalents of one invariable factor; there is nothing to choose between them.

Now let us consider our commodities as cargo rather than ballast. There is now something independent of their weight, to choose between them. Wheat may be wanted at the port where the ship is going; you choose it because it is needed. It is a question of needs. How many needs are there? You may say their name is legion; but we require to go back farther than that, to the *idea* of need—just as we have seen that there may be many weights but only one *idea* of weight.

The Criterion of Value

We have reached a stage in the world's history at which world-conferences admit one dominant criterion of policies,—the need of the human race. This is the fundamental principle to which the economics of trade-relationship must be referred and to which national considerations must be subordinated; that is, international trade-relations and international exchange problems have largely superseded the purely national problems.

We reach a simpler definition of

value .. .. *world-worth;*
and for *money* .. .. .. *the expression of worth;*
and for *price* .. .. *world-money-worth.*

Observe that money is not the expression of the *degree* of worth; there may be many degrees, as there are ounces, pounds, kilos, poods; but as there is an absolute weight, so there is absolute worth of world-wide application. Thus we have true comparison of the value of commodities.

This last phrase brings us to the ways and means of valuation. Here we must go warily. We are speaking of general principles, not of the complexities that in point of fact confront us. We require a symbol of worth by which fluctuating degrees of value may be reckoned. We might choose any commodity, and say, "Let that be our symbol;" and, having chosen it, consider it to represent an unalterable conception. This is the fundamental axiom, and it requires to be followed up in its simplicity before considering the complexities that follow.

Dependent upon the absolute nature of worth, there should be a proportionate equivalent of the material possessions of the world in worth tokens. Relativity, in the last resort, predicates an abstract and integral conception. Relative values imply an abstract conception of indivisible value. As relative values are expressed, for purpose of exchange, in terms of currency—as "price"—currency itself must be based upon an unchanging expression of value. It follows that, whatever the unit of value may be, multiplication does not affect its intrinsic worth, and division is impossible.

Universal Standard Required

In order that the legitimate effects of world-production and consumption may be proportionately represented in terms of currency, a universal standard of value is demanded. The most convenient manner of expressing value lies in the choice of a suitable material, the requirements being ease of distribution and indestructibility. If it appears that, owing to the volume of trade, the supply of the chosen materal is inadequate for the requirement, the choice of a second material to represent it is legitimate. Factors affecting such a choice are such as the

ratio of production of the two materials, which serves to indicate the ratio of value between them; also the adaptability of the satellitic coinage to individual national usage. The word "satellitic" is used to imply that the function of the second material, as currency, is absolutely dependent upon the material it is used to represent, and that it can have no fluctuating prerogatives of its own, neither can they be forced upon it.

The practical trouble with the world's currency to-day seems to be, (1) an insufficiency of real currency of intrinsic value, and (2), a clashing of national interests due to the unstable substitution of fictitious currency for real currency.

The need of the world to-day seems to be unification and equalization of trade-relations, and it also seems to follow that relief may be found in the universal adoption of silver as a basis of currency. And so the problem appears to have a two-fold aspect. First, we require to be released from the paper currency embroglio; and second, we need an adequate means for international valuation.

Augmented Metal Currency Needed

Looking at the facts of currency obligations, it would appear that, even if the whole of the world's gold were in Europe, a re-valuation of gold to permit of the absorption of excess paper currency would merely introduce international complications of immensely graver import than those that already exist; it could be only a national expedient, and it is world-finance that is sick. The supply of currency is insufficient; otherwise there would not be all this paper. And if the intrinsic value theory of currency is correct, the remedy lies in creating a substitute for gold to do duty for it in all countries, and especially in those where gold is not to be had.

It is not for the uninitiated to discuss problems such as the relation between the Bismarckian coup of 1873 and the present cataclysm of insolvency; and, maybe there is small hope of unanimous opinion even among the initiated in regard to the difficult and diverse problems of present day finance. But if the principles of inherent worth and of the common good call for an increase in the metal currency of the world (and this is the substance of my argument) expediency will win over habit, and means will be found to make our conventional tokens of worth serve more adequately humanity's need.

ANOTHER RAND?

The *Afician World* states that a five-stamp battery is being set up in the locality of the Masai Reserve near the border of the Tanganyika territory, were prospecting areas have been pegged for many miles along the course of the reefs . Whether the venture be successful or not, he would be a bold man who would assert that the resources of Africa for gold mining have been by any means yet ascertained. The Rand—which has produced, and may yet produce, more gold than any gold bearing area that has ever been worked — was discovered by a fluke. An edge like that of a tilted saucer, bearing gold outcropped, and was detected to contain gold. Had this not projected from the surface, the immense mass of gold bearing ore at depth would have remained one of the secrets of Nature.

1370 Per Cent

The E. J. Du Pont de Nemours and Company of Wilmington, Delaware, manufacturers of explosives and chemicals, estimate that their research laboratory has yielded a profit of $82,401,000 from 1912 to 1918, inclusively. This represents a yearly return of 1370 per cent. on their investment for research.

Letters From Readers

INDUCTION AND DEDUCTION

To the Editor,
Canadian Mining Journal.

The reference to induction in Mr. Campbell's article in your issue of September 7th suggests that a brief discussion of the complementary psychological processes, induction and deduction, may be of interest to readers of the "Journal." These scientific terms merely express more precisely the common processes of reasoning used, almost unconsciously, by every normal person, in his ordinary daily experience. Without induction in the widest sense, there would be no generalization, and little if any intellectual progress.

Induction is the mental process by which experience becomes of value. There would be no accumulation of the fruits of experience, no ripening of experience into sound judgment, but for this rational process. It is the intelligent aspect of experience—that wherein man differs chiefly from the lower animals, which are generally assumed to be incapable of consciously generalizing from their observations and experiences.

Induction, in any real sense, cannot lead to absolute truth. In its approach to certainty it is progressive. When it reaches certainty, it may cease to be real induction and become a mere shortened statement to avoid repetition.

Science is founded on, and built up by, induction. Engineering, based on science, advances with its progress. Without induction, therefore, there would, or indeed could, be but little advance in engineering.

Scientific use of induction springs from discernment of underlying principle. Hence, it may be used as the basis of prediction, within the limits indicated by the believed extension of the principle. Indeed, fulfilment of prediction is usually the best test of the accuracy of an induction.

But this use of induction brings forward its companion process, deduction, which is predictive, forward-looking, progressive, and without which induction would not get us very far. The two processes are inseparable. The one implies the other. They are respectively the backward- and forward-looking aspects of the same process. But deduction, being forward-looking, can only follow, it can never precede, induction. The human mind proceeds from the known to the related unknown.

Scientific use of deduction is also dependent on the discernment of principle. Logical deduction may be content with the statement of particulars which were already enfolded in the corresponding induction. But this use of deduction gets us nowhere. It is merely going in a circle. It was this fatal limitation which reduced to mere barren routine the scholasticism that preceded the Renaissance. The discovery or recognition of scientific induction, which, from the beginning, man had used unconsciously and therefore only to a very limited extent, was the first ray of light to penetrate the darkness in which men were then groping. Even yet, human progress is greatly impeded by the failure of the majority of our fellows to recognize clearly, and to use consciously and intelligently, a mental process which they unconsciously and gropingly use every day of their lives.

Careful, analytical thought will show that most of the recognized facts of experience are really conclusions

reached by induction. The mind becomes stocked with many of these in youth and is unaware in many cases of why or when they are accepted. The education of youth has consisted to a far too great extent in this "stocking" process, to the too frequent neglect of insight into how the conclusions were reached. Every teacher of science to beginners knows that the transition from this ordinary stock of knowledge to a conscious, critical extension of experience, with the ordinary student, is very gradual. The growth of science results from a conscious, systebatic, critical continuation or extension of intelligent experience, by the use of the twin rational processes, induction and deduction.

Scientific use of deduction, depending, as has been said, on discernment of wider application of principle, is progressive, constructive, aggressive; it stimulates growth of related, vital knowledge. Scientific use of induction and deduction, as contrasted with mere logical use of these processes, is largely dependent on insight. The author of the article alluded to is qiute right in speaking of "vision" (or insight) as characterizing the men who make use of scientific induction. But the "vision" in each case is neither less nor more than the natural result of discernment of the essential principle. He who does not, or cannot, discern the underlying principle in any given scientific induction or deduction must be denied the "vision."

It was thus through insight or "vision" that Dr. Miller, in the early days of Cobalt, by induction formulated the relationship of the silver ore deposits to the diabase sill. It was by similar "vision" and deduction that Dr. Bell made his startling discovery of the spectacular silver-bearing veins in Keeley Mine in South Lorrain, fifteen or twenty miles from Cobalt, where others, perhaps lacking Dr. Bell's "vision," had failed.

In a similarly striking example of insight into essential principle, by use of induction, our brilliant young geologists have quickly unravelled and stated the genetic relationship of the auriferous ore bodies at Porcupine and Kirkland Lake to their associated formations. Similarly, "vision" and deduction led to prediction of probable discoveries in like formations, probably the extension of these, in western Quebec—a prediction which, from reported recent discoveries in that area, appears to be well-founded.

Scientific use of induction, again, must receive credit for stating the relationship of Sudbury copper-nickel orebodies to the associated norite batholith. So also must scientific use of deduction be credited with the discovery of a large body of ore under 80 feet of muskeg in Levack township after several previous attempts by diamond-drilling had failed to find it; likewise with the discovery of ore under 100 to 200 feet of gravel east of Garson Mine.

A further example is the prediction made some years ago by Prof. Mickle, Mines' Assessor of Ontario, regarding the silver-bearing veins at Cobalt. The application of the principle or law of averages to such a case as this was very unusual, being less obvious than the illustrations already given. His general statement led to a prediction by him, based on deduction therefrom, which proved to be remarkably sound. The prediction was very startling and was probably received with many grains of doubt by mining engineers. Many of us at the time were denied the "vision," because we had not the insight to discern that this law or principle was applicable to this particular case.

For the mining engineer, who hopes to see farther than mere calculation of ore blocked out or indicated by drilling; who realizes that the future of the mining industry rests more on discovery than on any other single factor; and who knows that discovery seldom results from mere blind searching; the companion processes of reasoning—induction and deduction—are the most powerful aids he can invoke. As well may the shoemaker despise his last as the mining engineer disdain to use these most potent twin tools of the intellect.

These rational processes culminate in the law of the uniformity of nature—a sweeping induction that is lifting man out of the mire of superstition. But for this fundamental induction, on which every other scientific conclusion is founded, we would all still be trying to propitate the spirits, supposed by primitive peoples to control the many natural phenomena reacting on us. To these two rational processes we must attribute such progress as man has made in unravelling nature's secrets and in bringing her forces into subservience. To these we must also look, as the most efficient tools yet discovered for carving out his future destiny, by enabling him to continue his progress in understanding her laws, in controlling her forces, and in co-ordinating his own activities with hers.

C. V. CORLESS

Coniston, Ontario, September 14th, 1923.

POSITION OPEN IN DEPARTMENT OF MINES.

The Civil Service Commission, Ottawa, announce that applications will be received up to October 11 th for the following position:

6058—An Editor, Grade II (Male), for the Administrative Branch of the Department of Mines at Ottawa, at an initial salary of $2,400 per annum.

Duties.—Under direction to edit reports bulletins and other publications of the Department of Mines; to correct errors in text as well as in grammer and punctuation and on occasion to alter or rewhite reports; to confer with authors of reports; to supervise proof-reading; to specify make-up and other technical details; to be responsible for the preparation of tables of contents and indexes; to supervise subordinates; and to perform other related work as required.

Qualifications required.—Education equivalent t graduation from a University of recognized standing; a good working knowledge of the general outlines of applied geology and mining engineering, and of the technology of one or more of the following:—ore dressing, metallurgy, fuel testing and ceramics; a thorough command of English; ability to write technical papers, and to edit and to prepare for publication, scientific reports; discretion, tact and good judgment

This position will be filled temporarily at present, but should a permanent appointment later be required, the temporary incumbent may be certified in the position providing his services have proved satisfactory to the Department while temporarily employed. In the case of a permanent employee, the initial salary of $2,400 will be increased upon recommendation for efficient service at the rate of $120 per annum until a maximum of $2,880 has been reached.

Preparations are being made in the Norwegian Mint for the striking of a new coinage which will only be valid as currency in Norwegian territory. The coins will be of nickel, and will probably have a hole through the middle.

In the United States alone, one hundred million dollars worth of copper is refined by electricity as a result of the genius and research of Davy and Faraday

McIntyre Porcupine Mines and Management

By ALEXANDER GRAY

The Eleventh Annual Report of McIntyre Porcupine Mines is a compliment to the men who made it possible. No matter what the actuaries may think or say about mines with gross ore reserves of $8,514,800 and a market capitalization of $12,800,000, they concede to the management all it is entitled to for having brought the properties and plant to their present status. The McIntyre directorate will be accorded all due credit for having sustained General Manager Ennis, the proof of progress being exhibited in the mining position, the enlarged milling plant, the treasury, the general outlook—even the Blue Diamond coal venture that is involved in the further purchase of the Canadian Coalfields, Limited.

By themselves, Porcupine Mines of the McIntyre company are an outstanding example of what can be achieved in spite of recurring handicaps. With current assets approximating $1,000,000, liquid reserves amounting to $1,558,199.84, investments of $619,494.23, and the gross values of the ore reserves conservatively estimated at $8,514,800, speculative factors are provided for those who are not in a hurry. Undoubtedly the coal properties are a slow asset, and the $1,000,000 commitment against the property of Canadian Coalfields is not to be evaded unless McIntyre Directors find it possible to create a subsidiary organization to deal with the Blue Diamond as well as Canadian Coalfields.

Encouragement and Difficulties

Otherwise the McIntyre gold areas have the elements of prosperity succinctly pointed out by President Bickell. "The lower horizons have only been explored to a very limited extent, due to the re-occurrence for the third successive season of an acute hydro-electric power shortage which greatly curtailed our development programme and production. In view of such a serious handicap, the fact that our ore reserves have been increased in excess of a million dollars is worthy of note." "The mill is presently treating an average of 1,000 tons daily, and we have every reason to expect that the present year will prove to be the most prosperous in the Company's history."

How grievous were the power difficulties, is set forth by General Manager Ennis. "The new mill addition," he writes, "was ready to operate on November 1st but, due to a shortage of hydro-electric power, only 50 per cent of it was put into commission. There were further reductions in power, with consequent reductions in tons milled, until in April only 250 tons per day were being treated. Full power was available again on May 3rd, and in that month 28,085 tons, and in June 27,925 tons were handled."

Shortage of hydro-electric power, generation of steam power, minimized operations, automatically precluded the reduction of working costs and prevented the management from doing all it wished to do in the matter of development. Notwithstanding this, after treating 240,615 tons, averaging $9.96, having a gross value of $2,397,303, of which $2,249,741.63, $9.35 per ton or nearly 94 per cent., was recovered, the ore reserves, as President Bickell emphasizes, were increased more than a million dollars in value, and the broken ore in the stopes at the end of the year amounted to 155,881 tons, compared with 130,136. Taking this into consideration along with the 27,000 feet and more of development and exploration work, the operating cost of $5.54 per ton milled is a mark of efficiency.

Deep Level Mining

The present and immediate future of McIntyre Mines rests securely as to continuous and increasing production, in the area between the 1,000 and 2,500-ft. levels. What there is or may be at greater depth is only a subject for conjecture. The 242,891 tons milled in the year ended June 30, came from the section between the 1,000 and 2,125-ft. levels. "What work has been done," writes Mr. Ennis, of the lowest levels, has indicated "no change in the favourable geological conditions." The certainties, without indulging in projections, lead Mr. Ennis to abide by his judgment that the present lower levels "should add materially to the ore reserves of the mine in vein systems Nos. 7, 9, and 10, with the possibility of other vein systems being found."

McIntyre's record for the year was the best of the eleven years since milling began. The gross value of its production was $2,397,303. The average value of the ore milled was somewhat lower than it was since 1919. Mr. Ennis aims at uniformity over the years and his confidence in the properties is manifest. To the end of the eleventh milling year, $16,089,020.20 was produced and $15,222,411.09 recovered, the average of 1,586,736 tons treated being $10.14, of which $9.59 was recovered. The average of the further 858,504 tons in the estimated ore reserves is $9.92. Obviously the record to date "is a reasonable check" on what Mr. Ennis is assured of in the section below the 1,000 foot level. He gives chapter and verse for what he has, making allowances for dilutions. The case for the McIntyre is clearly stated by him, in this way:

No. 5 Vein:—

The stopes in No. 5 Vein on the 1,250 and 1,375 produced 66,902 tons of ore of $11.00 grade. Stoping operations are being carried out on the 1,500 in this vein but no development has been done below this level. From stopes in North No. 5 Vein System there have been drawn 43,523 tons of $10.30 ore. These ore bodies are irregular, the stopes ranging in width from 8 feet to 40 feet and usually of high grade ore. On the 1,250, 1,375 and 1,500 levels No. 2 lense of this system was opened up in length varying from 105 to 300 feet in ore 10 feet wide, averaging $10.50. On the 1,375 and 1,500 No. 3 lense 35 feet north of No. 2 has been opened up a distance of 150 feet in ore of $16.00 grade. No. 4 lense 75 feet north of No. 3 was opened up on the 1,375 and 1,500 a distance of 164 feet, 15 feet wide of $25.00 ore. These ore bodies are lenses of disseminated pyrite in basic schist adjacent to tongues which extend upward from an underlying body of porphyry. These porphyry tongues rake to the east from 40 to 50 degrees and the adjacent schist offers favourable areas for the occurrence of similar ore bodies.

No. 6 Vein:—

No. 5 Shaft passed through No. 6 Vein at 2,125 and 108 feet of drifting shows ore of $11.00 grade. This vein lies south of a porphyry tongue and has all the characteristics of the North No. 5 Vein.

No. 7 Vein:—

This vein consists of closely paralleling lenses which must be mined as one continuous ore body with consequent dilution. On the 1,500 foot level 573 feet of advance was made in ore 5 feet wide assaying $8.00 per ton. On the

1 625 foot level, 695 feet of advance was made in ore 5 feet wide assaying $8.50 per ton. On the 1,725 foot level 952 feet of advance was made in ore 9 feet wide assaying $8.50. On the 1,875 level 980 feet of advance was made in ore 7 feet wide assaying $8.00. On this level No. 7 Vein is opened up for a distance of 1,500 feet in ore averaging 10 feet wide with an average value of $10.60 per ton. No drifting has been done on No. 7 Veins below the 1,875 foot level.

No. 8 Vein:—

No. 8 Vein mentioned in last year's report has not been found below the 1,500 foot level and being of low grade on the 1,375 and 1,500 foot levels no work has been done on it.

No. 9 Vein:—

No. 9 Vein has been opened up on the 1,875 foot level for a distance of 479 feet, showing ore of an average value of $10.20 per ton over a width of 9 feet. At 580 feet south of No. 5 Shaft No. 9 Vein is exposed on the 2,125 foot level, assaying $21.80 over 8 feet. 60 feet of drifting has been done, averaging $25.40 over a width of 8 feet. Crosscuts are now being driven south from No. 5 Shaft on the 2,000, 2,250 and 2,375 foot levels to intersect this vein.

No. 10 Vein:—

Crosscuts from the lower levels have not advanced far enough south to intersect No. 10 Vein. Diamond drill hole No. 359 passed through this vein on 1,875 horizon showing 10 feet of ore assaying $9.60.

HOW TO DESTROY DAMAGED EXPLOSIVES

BY J. H. HORLICK, Jr., in *Explosives Engineer*

It is sometimes necessary to destroy explosives that have deteriorated until they are no longer useful or that have become dangerous because of leaking ingredients. The only sure methods of destroying these explosives are to burn or to explode them. However, exploding is not practicable because of the violent disturbances produced by detonation in the open. Burning, therefore, is the safest and most effective method.

When destroying high explosives they are first taken to a safe place and the cartridges removed from the cases. The best practice is to remove the explosives from the wrapper, or slit and spread the cartridges apart. The explosives are then spread in a thin layer on straw, paper, excelsior, or other inflammable material. If the wrappers are removed they should be spread out and burned on the same pile. A deep layer of explosives is dangerous, because when the material on top or on the edges starts to burn there may be sufficient confinement to cause the underlying material to explode instead of burn. Some high explosives are so difficult to ignite that it is necessary to moisten them with kerosene before lighting; in fact, the use of kerosene is advisable in every instance, because when sufficiently saturated with kerosene there is virtually no probability of explosion. Under no circumstances should the operator remain near enough to be in danger if an explosion should occur.

One way of igniting the explosives is to lay a trail of paper or excelsior which, when lighted, acts as a fuse and allows the operator to gain a safe distance before the flame reaches the powder. If blasting powder is at hand, a more positive method of ignition is to insert a fuse or an electric squib in a short train of blasting powder in contact with the thin layer of explosives. After the blasting powder is ignited by the fuse, or electric squib, it quickly causes the other explosives to burn.

In destroying large quantities where repeated burnings are necessary, explosives should not be poured or placed on the same ground that has been used for a previous lot, because there may be sufficient heat remaining to ignite them. The empty cases should also be burned. If they show signs of having been in contact with leaking ingredients, the boards should be piled in a long low heap, in order to reduce to a minimum the possibility of an explosion. The safest practice is to do this, even if stains are not visible.

Under no circumstances should the attempt be made to destroy high explosives by placing them in water, because nitroglycerin and some other explosive ingredients are not soluble in water, and are, therefore, not destroyed by immersion.

Black blasting powder may be destroyed by burning in a similar manner to that described for high explosives; the same precaution of avoiding a deep layer of powder should be observed. The powder may be ignited either by a trail of paper, a fuse, or an electric squib. Blasting powder can be made non-explosive by immersing in water if it is permitted to remain long enough for the soluble ingredients to dissolve. A fairly large body of water should be used for this method.

When properly stored, blasting caps seldom deteriorate sufficiently to be unfit for use. The usual cause for deterioration of standard blasting caps is excessive moisture. The chief danger in destroying them is from pieces of the copper capsules flying through the air; the sharp flying fragments readily imbed themselves in the flesh. A convenient method which avoids this danger is to place the caps in a hole with a primed dynamite cartridge, and cover them well, preferably with sand. Detonation may be accomplished by means of a good cap and fuse, or an electric blasting cap. Before being destroyed, electric blasting caps should have their wires cut off an inch or two from the capsules, because the wires are likely to cushion the shock and prevent the explosion of all the caps. The deterioration of the caps is no excuse for carelessness; they should be handled even more carefully than caps in good condition.

GUANO STILL IN USE

In spite of the competition from rock phosphate, the guano of the islands of the coast of Peru that used to be such an important source of phosphate fertilizer is still used. It is now gathered as a crop, being obtained from the islands successively while it is allowed to accumulate on the others.

CARBON BLACK IN THE UNITED STATES

The output of carbon black in the United States in 1922 was almost 60,000,000 pounds, worth $5,500,000, or an average of about 9.1 cents per pound. A large part of this was used as a filler for rubber tires.

OIL FROM LIGNITE IN GERMANY

Germany's production of oil from the distillation of brown coal and lignite is growing by leaps and bounds. Low-temperature carbonization, followed by briquetting, is being practised successfully in several new plants of large capacity. It is predicted that Germany will, in the not far distant future, produce by this means all the mineral oil she requires.

The same raw material — lignite beds at or near the surface, amenable to mining by steam shovel—is available in abundance on the Canadian prairies.

Ontario's Mineral Production

First Six Months of 1923.

Last week the report of the Ontario Department of Mines on the Province's mineral production for the year up to June 30th was made public, as follows:

SUMMARY OF ONTARIO'S MINERAL PRODUCTION — FIRST HALF OF 1923.

(Comparative figures are given for the corresponding period in 1922. Tons throughout are short tons of 2,000 pounds.)

PRODUCT		Quantity (6 mos.) 1922	Quantity (6 mos.) 1923	Value $ (6 mos.) 1922	Value $ (6 mos.) 1923

* Copper and nickel exported in the form of matte valued at 10 and 25 cents per pound, respectively.
& Iron ore figures in the table include only exported product or shipments to points other than Ontario blast furnaces.
&& Figures in the table represent proportional output and value of pig iron produced from Ontario iron ore.
** Includes residues marketed.

General Remarks

Returns received by the Ontario Department of Mines from the mines, smelters and refining works of the Province for the six months ending June 30th, 1923, are tabulated in the preceding table. Compared with the figures for the corresponding period in 1922, the total production shows an increase of 27.6 per cent. The outstanding feature is the marked increase in production of nickel and copper. Nickel-copper mines, smelters and refineries of the three companies are all in operation again, indicating a revival in business following the stagnant period succeeding the Great War. The total metallic production shows an increase of 37.9 per cent.

Non-metallic minerals show an increase in output of 20.8 per cent, increases being noted in feldspar, graphite, gypsum, iron pyrites, mica, natural gas and petroleum, quartz and salt.

Gold

The small decline in gold production was due to an acute shortage of hydro-electric power during the first four months of the year. This situation has been remedied by the completion of additional power plants on the Mattagami and Montreal Rivers, while other hydro-electric plants to serve Ontario's gold mines are now under construction on the Quinze and Abitibi Rivers. With ample power available, increased milling capacity at both Porcupine and Kirkland Lake and the addition of new producers, it is expected that production of gold in Ontario for the full year 1923 will be considerably in excess of the 1922 output of one million

ounces. In addition to the values given in the table, mines reported receiving for bullion marketed the sum of $60,269 by way of exchange premium which averaged 1¾ per cent. for the half year.

GOLD PRODUCTION — FIRST HALF OF 1923

Source	Ore Milled	Bullion Shipped Gold	Silver	Total Value
	Tons	Ounces

Silver

Shipments from the mines at Cobalt and outlying silver areas show an increase as compared with 1922, the figures being 4,938,364 and 4,774,666 ounces, respectively. South Lorrain, about 18 miles south-east of Cobalt, has attracted much attention owing to the richness of the ore being mined by the Keeley and Lorrain Operating (Mining Corporation of Canada) companies, the combined output being 1,283,026 ounces of silver. In addition the South Lorrain ore carries a high cobalt content. The success being experienced in this area has stimulated prospecting throughout Ontario's silver producing areas.

The average New York price of silver for the half year was 66.05 cents per fine ounce compared with 67.34 cents in 1922. Shipments of silver ore and concentrates over the T. & N. O. Railway were 641 tons to points in the United States, and 1,041 tons to the Ontario silver smelter at Deloro. Shipments of silver by the largest producers are given in order: Nipissing,1,620,546 ounces; Keeley, 826,814; Coniagas, 711,617; O'Brien, 488,571 Lorrain Operating Co. 456,212; Mining Corporation, 409,994. A summary of shipments is given hereunder:

	Ounces	Value $
Cobalt, South Lorrain and Gowganda	4,843,316	3,217,569
Contained in gold bullion	71,963	47,496
Recovery from Nickel-Copper refining	23,085	15,144
Total	4,938,364	3,280,209

Refineries.—Two refineries in Southern Ontario treat silver ore and recover silver, cobalt, nickel, arsenic and copper. A total of 4,521 tons of ore, concentrates and residues were treated during the six months. The Coniagas Reduction Company has operated the plant of Coniagas Alkali and Reduction Company since Feb. 20th, when the latter company ceased work. Metallic nickel and oxide recovered is small compared with the output of nickel-copper refineries, shipments being 32,855 lbs. of nickel and 11,468 lbs. of oxide, in addition to unseparated cobalt-nickel oxide. Residues are valuable chiefly for their cobalt content. White arsenic, cobalt and cobalt oxide shipments are noted in the tabl The Deloro Smelting and Refining Company at Deloro operates an insecticide plant.

Nickel and Copper

Production from the Sudbury area shows a mark increase over the 1922 output, indicating a recovery from the over-stocked nickel market following the Great War. The Mond Nickel Company operates a plant at Clearfield, Pa., for the production of malleable nickel and the International Nickel Company has erected at Huntington, W. Va. a rolling mill for production of nickel and monel metal products. Monel metal — an alloy of nickel and copper in the proportions found in the matte turned out by the Sudbury smelter — is finding wide use for a great variety of purposes. After a prolonged shut-down the mine, smelter and refinery of the British America Nickel Corporation resumed operations during the second quarter of 1923.

During the period 457,269 tons of ore were smelted by the three companies for an output of 25,238 tons of nickel-copper matte containing 26,885,458 lbs. of nickel and 13,574,235 lbs. of copper. Exports of matte were 9,142 tons of which 4,196 tons were shipped by the International Company to Huntington, W. Va., and 4,946 tons by the Mond Company to Wales. The two Canadian refineries treated 15,145 tons of matte, recovering therefrom 10,275,563 lbs. of nickel, 4,596,359 lbs. of nickel oxide and 6,053,419 lbs. of copper in addition to gold, silver, platinum and palladium noted under their respective headings or in the table on page 765.

Iron Ore and Pig Iron

During the half year 2,508 short tons of briquettes, beneficiated magnetite, from Moose Mountain were shipped to the Steel Company of Canada, and 6,486 tons to points other than Ontario blast furnaces, the total value being $32,429. The Iron Ore Committee appointed by the Provincial Government to investigate the possibilities of a wider use of Ontario's low grade iron ores has submitted its report which will be printed in the near future.

In January only three blast furnaces in Ontario were in operation. The number was increased to six for May and June. The Algoma Steel Corporation at Sault Ste. Marie and the Steel Company of Canada at Hamilton charged to blast furnaces 11,138 short tons of domestic ore and 555,166 tons of "Lake" ore, or a total of 566,304 tons, less than 2 per cent being Ontario iron ore. Pig iron production was 296,739 long tons divided as follows: basic 166,224; foundry 87,697; and malleable 42,818 long tons; the total valuation at $29.70 per long ton being $8,813,148.

Ferro-silicon was produced by the Electro-Metallurgical Company of Canada, formerly Electro-Metals of Welland, and also as a by-product by three companies in the Niagara peninsula who manufacture artificial abrasives, the total output being 13,013 long tons.

Lead

Ontario's only operating lead mine and smelter are situated at Galetta on the Ottawa River and are operated by the Kingdon Mining, Smelting and Manufacturing Company. A blast furnace has been installed to treat slag and flue dust. A small recovery of lead is made from Cobalt silver ores and concentrates shipped to United States refineries for treatment, and returns for this recovery are received annually. The average New York price for the half year was 7.75 cents per pound. Total Ontario shipments were 1,784,749 pounds valued at $120,694.

Non-Metallic Minerals

As noted under heading "General Remarks" the total increase over 1922 in valuation of non-metallic minerals shipped was 20.8 per cent. Although no apatite shipments are reported there is a good local market at Trenton, where the Chemical Products Company manufacture sulphuric acid and acid phosphate.

Arsenic sales were not as large as in 1922 but the average price increased from 8½ cents per pound for the full year of 1922 to 12½ cents for the first half of 1923.

Figures of feldspar production are incomplete. There are two grinding plants operating in the Province. The bulk of the production, however, is exported in crude form. Feldspar fines are used as a pebble dash for stucco.

Gypsum shipments were as follows: crushed and ground, 27,407 tons; calcined, 1,174 tons; calcined gypsum used in gypsum products such as plaster board, blocks and alabastine, 19,367 tons. Mines and mills are located at Caledonia and Lythmore in Haldimand county.

The increased tonnage in mica shipments is due to scrap mica, now used largely for the manufacture of ground mica which has a great variety of uses such as covering ready roofing, as a powder for applying to automobile tires, in lubricants and in the electrical industry for insulating purposes.

Natural gas production shows a small increase in quantity over 1922 figures and a larger increase in value which has been placed at 56 cents per M. cubic feet. The drilling of new wells, prevention of leaks, and general methods of conservation explain the present situation as regards natural gas.

Petroleum shows a small increase in output but the average price was $2.76, as compared with $2.88 during the corresponding period of the previous year. The price rose from $2.38 at the beginning of the year to $2.98 on Feb. 20th and declined by 10 cent drops to $2.48 on June 29th. The valuation in the table does not include the bounty of 52½ cents per barrel paid by the Federal Government amounting to $41,107.

Quartz production shows an increase, reflecting greater activity in steel making, ferro-silicon production and the nickel-copper industry which absorb the bulk of the output.

Salt sales of 96,207 tons includes the salt equivalent (39,217 tons) of brine used in chemical works. The grades of salt marketed were as follows: table and dairy, 20,487 tons; fine, 17,825; coarse, 15,251; land, 2,030 and pressed blocks of domestic manufacture, 1,397 tons.

Talc production showed a marked decline as compared with 1922 although a larger percentage of the finer and more valuable grades were marketed. The main output comes from Madoc.

Structural Materials and Clay Products

The itemized list includes Portland cement, brick, tile, pottery and sewer pipe, lime, sand and gravel, sand-lime, brick and stone. No statistics were obtained from producers, the estimated value being based on the relative building activity as deduced from Ontario building contracts awarded. McLean Building Reports show Ontario contracts totalling $84,020,000. for the first half of 1923 as compared with $74,586,900 for the corresponding half of 1922, an increase of 12.6 per cent. The City of Toronto accounted for $18,049,732 outstripping all previous records, and the Province as a whole is credited with over 50 per cent. of the entire Canadian contracts awarded. Building permits in 35 Ontario centers as reported to the Dominion Bureau of Statistics were $37,754,678 for 1923 and $36,213,035 for the first half of 1922 or an increase of 4¼ per cent. Prices of building materials stiffened as spring advanced, but receded somewhat in June. Mortgage money and building funds appeared to be ample for all construction requirements.

RESEARCH MAKES MONEY

A successful and highly remunerative series of researches is described briefly in a recent issue of *Chemical and Metallurgical Engineering*, thus:

Why do clear-thinking, well-informed business men who hold the stock or compose the directorates of companies in our chemical engineering industries so frequently disparage a policy of research? An old riddle which is growing more perplexing as it ages! To regard a technical staff as a semi-liability at best, to dispense with it whenever storm clouds gather on the business horizon—such is altogether too frequently the creed of those who pass upon expenditures. No more clear-cut evidence of such folly, or rather the wisdom of the maintenance of research, has come to our attention recently than the remarkable story of achievement made by one of the great yeast companies. This story is at once an inspiration to the research worker and a rebuke to those whose first thought is to reduce the technical staff in time of financial difficulty.

A few years ago yeast was made by this particular company from a cereal mash on an enormous scale and in eleven plants. About one-quarter of the grain was converted to yeast; from the mash alcoholic beverages and allied products were produced which yielded sufficient revenue to make possible a very low margin of profit on the yeast. Then came our entrance into the war. Edible cereals could no longer be used. Research found a manner of using oats as a substitute. Labor cost rose as high as 260 per cent above the pre-war level. As an offset to this, research developed a process to increase the yield to a figure previously unheard of.

Then prohibition came, seemingly to cap the climax. Competition with industrial alcohol makers could not be met with the costly high-grade grain alcohol produced by this process. Yet without this market the cost of yeast must be substantially increased. Again after a real struggle on the part of the research staff in a comparatively unknown and poorly charted field of chemistry the answer was found—production from new materials with the evolution of no alcohol and of almost no other side products. The net result of its research, which was well paid for, enabled this company to maintain its retail prices at pre-war standards through years of rapidly shifting economic conditions. Its process reached an efficiency of practically 100 per cent conversion of raw materials to yeast. Its product was improved, its sales were increased, its research facilities developed to the highest point. And all this through a period when many firms were endeavoring to weather the storm by putting a sign over the laboratory door, "This Way Out."

We have cited other similar instances; we shall cite more. Research, despite the many kicks it has had, is alive and growing. Here is added justification for our contention that it is indispensable in trying as well as in prosperous periods. Properly directed, there is no better manner of insuring increased dividends.

THE MINING DISTRICTS

By THE JOURNAL'S CORRESPONDENTS

NORTHERN ONTARIO

Argonaut — During the last few months there has been a certain amount of doubt expressed as to the results being obtained by the Argonaut Mine in Larder Lake. According to recent public announcements, however, the company appears to have solved its metallurgical problems. The ore contains a considerable amount of copper. Oil flotation was tried, but at first succeeded in obtaining only a comparatively low-grade concentrate. Recent work, however, has resulted in copper concentrate of about 20 per cent., carrying a considerable amount of gold, and this makes a satisfactory shipping product. The recovery is stated to be approximately $11.00 a ton from a $12.00 ore. The mill is at present treating approximately 60 tons a day, although it has a rated capacity of about 200 tons a day. A new compressor is being added to the mine equipment, which will permit the company to carry on more underground work.

Kirkland — A special general meeting of the shareholders of the Tough-Oakes Gold Mines, Limited, was held in Toronto on September 12th. This meeting was called for the purpose of ratifying several by-laws that had been passed by the Directors. The most important of the by-laws is one providing for the changing of the company's name to the Tough-Oakes-Burnside Gold Mines, Limited, and increasing the capital from $3,000,000 to $5,000,000, the shares having a par value of $1.00 each, instead of $5.00. The directors are authorized to sell the unissued capital stock after the increase has gone into effect, at a discount of not more than 55 cents a share. Another by-law provides for the purchase of five claims in the Kirkland district. The Tough-Oakes and Burnside properties are controlled by the Kirkland Lake Proprietary of London, and this new amalgamation will consolidate the company's interests in the Kirkland district. Recent work on the 800-foot level from the Tough-Oakes shaft is reported to be satisfactory.

Among the cases to be heard before the Mining Commissioner in Kirkland Lake on September 18th is a dispute between the Teck-Hughes and the Kirkland Gold regarding the disposal of the latter company's tailings. Earlier in the year the Commissioner gave permission to the Kirkland Gold respecting the temporary deposit, but the Teck-Hughes claims that its rights are being infringed and asks for an order restraining the Kirkland Gold from depositing tailings on the Teck-Hughes ground and compensation for damages that the company has suffered. During the month of August the Teck-Hughes produced $89,131, as against $80,500 in July.

It is announced that the capital of the Hunton-Kirkland Gold Mines Limited, has been increased from $2,000,000 to $4,000,000. Cross-cutting is being carried on at the 375-foot level in an effort to locate the faulted extension of the vein which showed some ore on the surface.

The Lebel-Lode announces the offering of 100,000 shares of treasury stock by public tender. The company's property consists of 173 acres adjoining that of the Continental Mines, and it is hoped to obtain sufficient money to carry on an extensive development campaign. The capitalization of the company is 2,000,000 shares, of which only 659,000 have been issued.

Diamond drilling will be started on the Sylvanite property, in an effort to locate the faulted extension of the main vein. An ore-shoot 200 feet long has been developed but is faulted at both ends.

South Lorrain — During the month of July the Lorrain Operating Company produced 130,120 ounces of silver. This company is owned by the Mining Corporation, which holds the South Lorrain properties. It is expected that the new 550-foot shaft will be in operation in about two weeks. The Mining Corporation has completed preparations for its work in Gillies Limit. A certain amount of surface work has been done, but it is understood that a shaft will be started at once.

Cobalt — The McKinley-Darragh has sunk a shaft 30 feet deep on the Paul claims in the Gillies Limit, but it is understood that the results are not as satisfactory as surface showings indicated.

During the month of August the Nipissing mined ore of an estimated net value of $173,459 and shipped bullion of an estimated net value of $284,696. The value of the month's production was estimated at 63⅛ cents per ounce. The low-grade mill treated 7,153 tons and the high-grade plant 70 tons. The refinery shipped 451,595 fine ounces of bullion. There were no new developments of importance underground but stoping operations at the different shafts continued to be satisfactory.

Faulty Statistics — According to the report of the Ontario Bureau of Mines, shipments of silver during the first six months of the year amounted to 4,938,364 ounces, an increase of 160,000 ounces as compared with the corresponding period of the previous year. The shipments of silver by the different companies are all given, but this means very little, and in order to give an accurate idea of what is being done, the Government should show figures for production. The Nipissing and Mining Corporation both buy high-grade ore, and the Mining Corporation also purchases low-grade ores. The production of these ores is all credited to the company that makes the shipments, so that due credit is witheld from the actual producer.

Higher Wages — The International Nickel Company at Sudbury announces an increase in wages effective October 1st. Machine men have been raised from $4.25 to $4.75 a day, and this new rate will compare with $4.50 being paid in Cobalt and $4.80 in Porcupine. It is generally conceded that there should be a difference in the rate paid in Porcupine and Sudbury, and it is a question if the Porcupine operators will consider that the new rate established by the Nickel Company will not necessitate another raise in the gold camp. Cobalt operators, unlike the others, cannot afford to raise wages beyond the present level, and it may result in their losing a number of good men. It is unfortunate that this act on should have been taken

at present, because an increase of this sort does not effect the operating companies so much as it does those companies that are carrying on development work on new properties. Any increase in wages for this sort of work is an extremely important factor, and is often the determining point as to whether work will be carried on or not. It is understood that the Nickel Company is not short of men at present, but it desires to keep the men it has and to bring back a number of men who were forced to leave the district during the prolonged shut-down.

BRITISH COLUMBIA

Dease Lake Placers — The persistent efforts of operators in the Dease Lake Country to develop the hydraulic placer properties on McDame and Thibert Creeks, are receiving recognition from the Provincial Government. The old Cassiar trail, which was not in shape to permit of the haulage of any heavy plant or machinery for the last 50 miles from the Tooya River to Dease Lake, is being converted into a wagon road for the entire distance of 72 miles from Telegraph Creek, and a renewal of activity in these old-time camps is to be looked for.

Already, machinery is being taken in and there is a prospect that during the next season the value of the ground may be fully demonstrated by provision of the necessary water supply for hydraulic mining on a larger scale than has been yet possible.

By reason of these improved conditions, it is reported that George Adams has been enabled to interest capital in his praise-worthy enterprise on Thibert Creek upon which he has been working steadily for some years.

Bog Iron Ore at Alta Lake — Dr. Davidson and associates, of Vancouver, report that the market for the product of their bog iron deposits situated close to Alta Lake on the Pacific Great Eastern Railway is improving. Shipments are being made regularly to the gas works of Seattle and Tacoma for use in the purification of gas. They state that their iron ore has been found more satisfactory than material obtainable elsewhere and the prospect of the development of an important industry along these lines is bright. It is their hope, of course, that some definite action will be taken to establish an iron and steel industry, in which event, they believe, their iron deposits, because of their proximity to the railway and economy of extraction, would become of importance.

The principal deposit of this limonite ore occurs about half a mile west from the north end of Alta Lake and outcrops on the westerly edge of a large swamp at the foot of a thickly wooded hillside. Here several outcroppings occur within an area of about 450 feet in length and about 250 feet in width. The extent of the deposits has not been fully determined but the ore is exposed in several open-cuts. On the surface the ore usually is loose and earthy, but a few feet below it becomes more compact. To the west the mountain rises abruptly to a considerable height. The rock formation is schistose in structure and carries a high percentage of iron pyrites, from the oxidation of which the limonite apparently derives its origin.

A steam shovel and other equipment were installed in 1919, when a spur track was constructed to connect the mine workings with the Pacific Great Eastern Railway about half a mile distant.

Stewart — The Granby Consolidated Mining & Smelting Co., according to a statement from Stewart, proposes continuing its exploration of the George Group of claims on Bear River, Portland Canal. Dr. Bancroft has been making a thorough inspection of the property this summer and the Company is planning to proceed with extensive development next season. There has been some delay occasioned, it is explained because of the death of the owner, Richard George, and the necessity of awaiting the probate of the will before a clear title could be handed to the bank for placement in escrow.

Smithers Now a Mining Centre — Smithers, a few months ago a small and little known station on the Grand Trunk Pacific Railway some 200 miles east of Prince Rupert, is becoming rapidly a mining centre of importance and already it is a community of much interest in the West. Its proximity to Hudson Bay and Dome Mountains has brought it into the public eye. Early this year the Provincial Government began work on the construction of a road to the Henderson claims in the development of which J. F. Duthie had met with unusual success. While the men were at work and Mr. Duthie was making his plans for the summer's operations, the transportation and installation of plant, and so on, representatives of the Guggenheim interests had inspected and reported favorably on the properties, with the result that negotiations were instituted and control passed out of Mr. Duthie's hands for a substantial consideration. About the same time certain Dome Mountain prospects were taken over by the same interests. All this has served to concentrate attention on the district. Attention is directed to the fact that the mineral of Hudson Bay and Dome Mountains is on the same side of the Coast Range batholith as that of the Premier Mine. Prospecting consequently has been stimulated. New claims are being staked and meantime the exploration and development of the properties that have been the subject of the above transactions are proceeding actively. The construction of a road to Dome Mountain next year will be sought by those interested in the district.

Trail Ore Receipts — Ore receipts at the Trail Smelter. Consolidated Mining & Smelting Co., for the period August 22 to 31 totalled 5,349 tons. Shipments in detail follow:

	Tons
Blackrock, Northport	540
Company Mines	3,275
Cork Province, Zwicky	31
Knob Hill, Republic	153
Lightning Peak, Edgewood	3
Lone Pine, Republic Wn.	550
Quilp, Republic Wn.	482
Sally, Beaverdell	31
Silversmith, Sandon	284
Total	5,349

Gold Dredging on Peace River — The Peace River Gold Dredging Co. have been operating this summer on the upper waters of the Peace River. They have been using a drag line scraper plant. The Manitoba Peace River Gold Dredging Company have been working further down stream. From both sources good results are reported and it is said that the latter concern proposes if, values recovered continue until

the end of the season, putting a large gold dredge on the river. A small gold stamp mill was installed early this year at Mount Selwyn, close to the junction of the Findlay, Parsnip and Peace Rivers. The machinery was taken in from Prince George via the river route.

Britannia's Capacity is 75,000 tons — The Britannia Mining and Smelting Co., which started operations in February last after rebuilding its concentrator and completely re-establishing itself at Britannia Beach, is reported to have handled 75,000 tons of ore in the month of June. This is the predicted rating of the new mill. Some five hundred men are employed underground to maintain the maximum tonnage production.

Gold Strike Reported on Texada Island. — The Nutcracker Group of mineral claims, situated on Texada Island close to the Marble Bay Mine, is reported to have yielded recently some exceptionally fine looking samples of gold quartz. No authoritative word has been received regarding this strike, but the proximity of the property to the Marble Bay Mine, which was operated profitably for years, brings the story within the realm of possibility.

Accident at Trail — An electric ore train in the smelter of the Consolidated Mining & Smelting Co. was thrown upon the water main feeding the water jackets of the lead furnaces when the trestle over which it was running gave way beneath its 32 ton weight. The accident occurred on the morning of September 8th when the train was reversed to avoid collision with an approaching train. The train and its driver, Alexander Stephano, were thrown to the water main below. This was broken and Stephano's body was so lodged that the water played under heavy

Ainsworth — The Florence Mine, Ainsworth, has resumed operation after six weeks of idleness. The mill is handling about 60 tons of ore a day. It is estimated that $300,000 has been spent recently on underground and surface improvements, additions to plant, etc., among the latter being a new locomotive costing $10,000.

Coal Production During August — The coal production of the mines of the Province during the month of August 1923, totals 222,296 tons, an increase over the month of July of 9,489 tons, and an increase over the month of June of 36,136 tons. The production of the month of May was 59,984 tons lower than the production of August.

Of the total production for the month the mines on Vancouver Island produced 135,947 tons, a little over 61 per cent. of the total, and 3,316 tons more than was produced last month.

The Nicola-Princeton mines produced 21,591 tons, an increase of 4,870 tons over last month and nearly 10 per cent. of the total production.

The mines in the Crow's Nest Pass district produced 64,758 tons, an increase of 1,303 tons over last month's production and approximately 29 per cent. of the total production of the Province.

Of the mines of Vancouver Island, those operated by the Western Fuel Corporation of Canada show an increase of 4,181 tons over last month, while those operated by the Canadian Collieries (Dunsmuir), Limited show a decrease of 1,890 tons from last month's production. The Cassidy mine also shows a decrease of 388 tons, while the mines of the Nanoose Collieries show an increase of 1,537 tons over last month, and the mines operated by the East Wellington Coal Co., and King & Foster show a decrease of 44 and 80 tons respectively.

In the Nicola-Princeton district all the mines increased their production over last month, the Middlesboro Colliery by 1,910 tons, the Princeton Colliery by 947 tons, and the Coalmont Colliery by 2,013 tons.

In the Crow's Nest Pass District the Coal Creek Colliery shows a decrease of 1,434 tons and the Corbin Colliery a decrease of 50 tons under last month's production, but the Michel Colliery has an increase of 2,787 tons.

ALBERTA

The Trial Coal Shipments to Ontario — The coal shipped from Alberta to Ontario under the special rate of $7 a ton granted by the Canadian National Railways for a limited period is reported to be in strong demand. Howard Stutchbury, Trade Commissioner for Alberta, sent this word from the East, where he is busy distributing the 6,000 tons shipped for test purposes. As a result representations are to be made to the Federal Government with a view to obtaining an extension of the special freight rate in question. In this connection the Hon. Howard Ferguson, premier of Ontario, recently interviewed Sir Henry Thornton, president of the C. N. R., with respect to the facilitation of western coal shipments into Eastern Canada and is said to have offered some suggestions that were favorably received.

The Drumheller Strike — There is no word yet of the settlement of the coal miners' strike in the Drumheller District of the Province of Alberta. Wm. Sherman, president of District 18, U. M. W. of A., has ordered the men back to work, it being held that they are out in violation of their contract. At a recent mass meeting the men of the Drumheller and Wayne fields maintained that they would refuse to work until the operators consented to re-instate certain miners who were discharged some time ago.

NOVA SCOTIA

McLachlan Turned Down in Vancouver—Evidently J. B. McLachlan was not taken seriously in the West or he would have unhorsed Tom Moore and his vaulting ambition would have placed him in the saddle as President of the Trades and Labor Congress of Canada. Such no doubt was his aim when he left Nova Scotia, but he did not succeed, and wasn't even in the running. We might inquire if his failure was due to an insane miscalculation of his own power to move the multitude in his favor, or to an under-rating of the strength of President Moore, whose appeal is usually to the best that is in man and not to his worst and maddest passions. Was it due to the fact that outside of Cape Breton, (for on the mainland of Nova Scotia he has few friends), McLachlan has shown a lack of those qualities that attract men and stir them up to acts of mutiny and riot? More likely it was due to his entire ignorance of the methods that appeal to thoughtful men in carrying on business. McLachlan may find dupes in the West who are willing to become his instruments in a bad cause, but we very much doubt it. He perverted his office as District Secretary in Nova Scotia by using it to spread a pernicious and poisonous propaganda, and because of this was thrown out. He still persists in his pestilential campaign and

when Governments or other civil powers throw off their indifference and overcome their timidity and awake to their full responsibility, no place will be found for men who would wreck and ruin the country in the name of Socialism or any other radical movement.

Steel Works Busy — Not since the steel trade slowed down, after the war, have the Sydney steel works been so busy. It is too much, however, to expect that this condition will continue long, seeing that the steel industry of the United States is beginning to show signs of slackening. Another period of dullness will affect seriously the city of Sydney. It is mooted, however, that a fairly large rail order is in sight, which with present orders may help over the winter. A fourth blast-furnace is to be blown in to produce pig iron for sale. Orders for the products of the small mills are beginning to drop, and all indications point to reduced activities before long.

D. H. McDougall Resigns — The resignation of D. H. McDougall from the vice-presidency of the British Empire Steel Corporation is a distinct loss to the company. From the beginning of his connection with the coal and steel companies of his native province, twenty years ago, he has been allied consistently with the forces of progress. Since he undertook the active management of the new Corporation on its being formed two years ago, a notable improvement has been effected, particularly in the engineering branches. Mr. McDougall remains on the board of the corporation as a director. He will open offices as a consulting engineer after a brief vacation.

All Mines Re-Instated — After negotiations lasting several weeks, the last of the miners reported to have been "black listed" by the British Empire Steel Corporation for their part in the strike have been reemployed. Robert Baxter, once more on the board of the U. M. W. A., has been active on behalf of these men.

New Coke Ovens to Operate — Due to the increased activity at the Steel Works, as well as to the prospective market for coke as household fuel in the cities of the Maritime Provinces and Quebec, the new battery of 80 Koppers coke ovens is being warmed up for use. Two old batteries, totalling 120 ovens, are already in use. For domestic use the coke does not require to be so hard as for blast-furnace use; hence more volatile matter can be left in it, which means that it can be treated a shorter time in the ovens, and hence a larger production obtained from the ovens.

Imperial Oil Company Buys Benzol — A contract has been signed by the Imperial Oil Company to take the whole benzol output of the by-product plant at Sydney. This benzol is an excellent motor fuel, and has been obtainable by employees of the British Empire Steel Corporation at a reduced rate. Owing to the new contract, this privilege has been withdrawn.

Coal Output Well Above Last Year — In spite of the cancellation of coal contracts in Montreal and elsewhere due to the recent strike at the mines, 500,000 tons more coal than last year will be delivered in the Montreal market. At present the collieries are not busy, but are maintaining a fair output. The heavy coal stocks piled at the different collieries last winter are not yet all loaded away, there being 100,000 tons still at Sydney Mines and about 50,000 tons on No. 2 coal floors. This must be all shipped before winter sets in, to make room for fresh mined coal. Everything points towards a rather inactive season between this and the New Year in the coal industry. What the coming year has in store for the trade will depend largely on the condition of general business throughout Canada and the United States.

TUNGSTEN ORES

Tungsten ores are found along with tinstone, and also in quartz veins in gold regions. In Nova Scotia, the quartz veins in which the tungsten ores are found are mostly barren of gold; but in the Porcupine area, Ontario, schulite has been found in considerable quantities, closely associated with the gold; and the tungstite of the Kootenay Belle, B. C., carries gold values. The quartz veins in gold regions should be carefully examined for tungsten minerals, especially those veins of "bull" which appear to be unmineralized. Scheelite, even in considerable quantities is easily overlooked. Wolframite is more easily spotted.

In panning for gold, a very heavy white or yellowish tail may be scheelite, or a dark brown tail may be wolframite. Where gold ore is being concentrated on Wilfley or other tables, scheelite or wolframite would appear with the other heavy minerals. It is always possible that, in some exceptionable case, it might pay to save the tungsten mineral as a by-product.

MESABI SINTER

The Mesabi Iron Company at Babbit, Minnesota, has been producing sinter steadily. One of the large users is Henry Ford, who uses this high-grade material to mix with the low-grade limonite from his Imperial mine in the blast-furnaces at River Rouge.

Sink your Shafts with "Jackhamers"

REG'D THE WORLD OVER.

SHAFT sinking perhaps more than any other phase of mining has benefited by the "Jackhamer." These one-man, hand hammer drills are ideal for down-hole drilling and for work in close quarters.

Today many mines are using the heavier types of "Jackhamer" drills — "DCR-23" and "DDR-13" —because of their power, speed, and ability to drill deeper holes. These types use 1 or 1⅛-inch steel. They were built for shaft sinking.

"Jackhamer" drills are made of forged steel, have hole-blowing device, strong steel retainer, rubber grip handles and automatic lubrication system — features which have marked the superiority of the "Jackhamer" since its introduction.

"Jackhamer" drills are now made in five weights. The three largest ones may be used with either steam or compressed air. They may also be equipped with or without arrangements for feeding water as well as air through the drill steel to the bottom of the drill hole to lay the dust and remove the cuttings.

Ingerso

Compressors **Rock Drills** **Sharpeners**

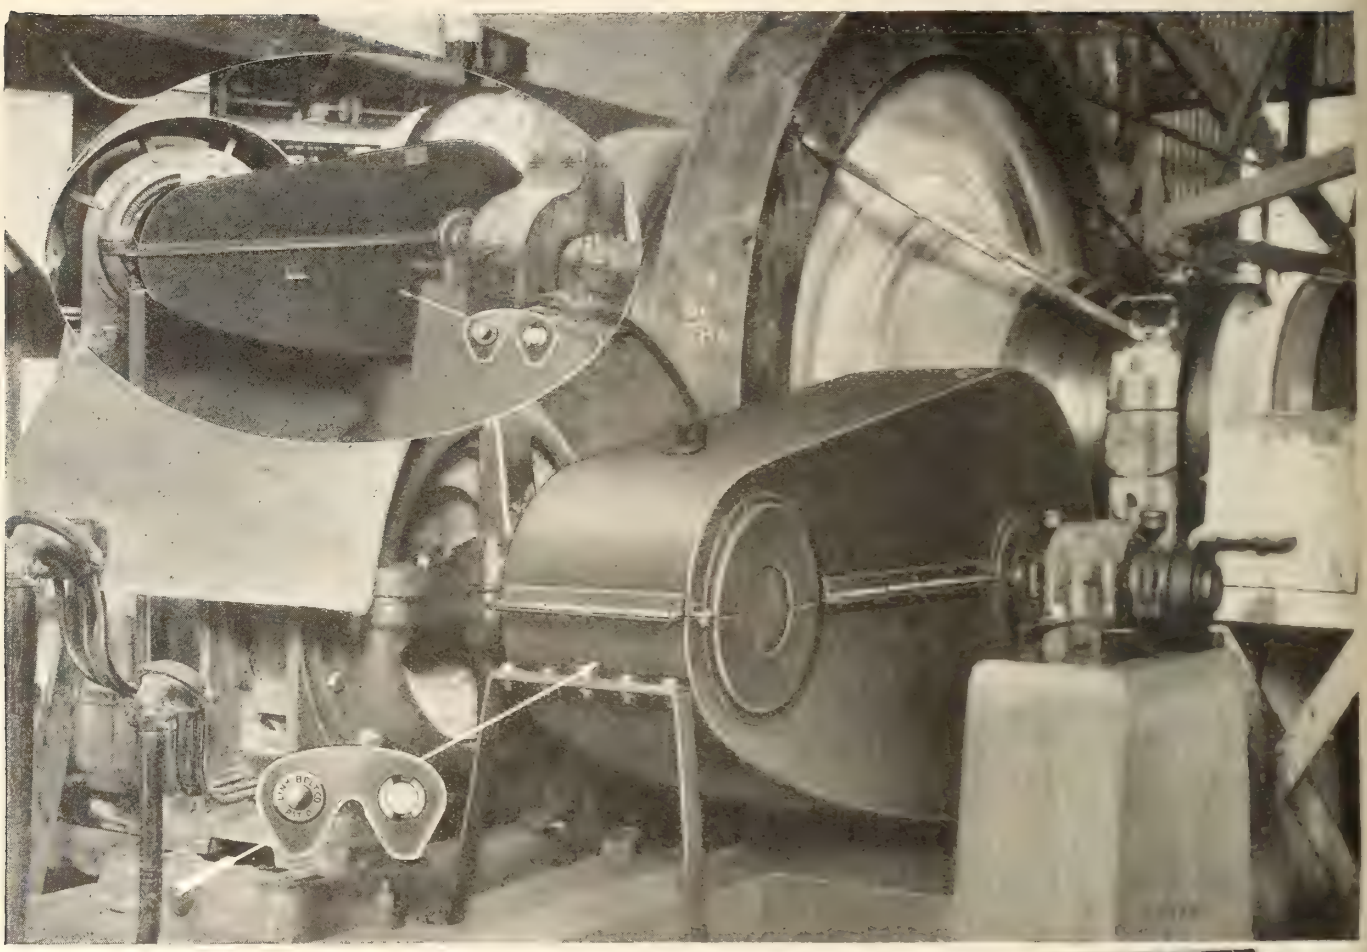
Although "Jackhamer" drills are principally used for down-hole drilling, and for service where the machine may be held in the operator's hand, mountings are made for the three larger sizes so that they may be used for incline raises or other work where heavier drills are clumsy and difficult to set up. They may also frequently be used to advantage for regular drifting and tunnelling work.

It requires only a few moments to mount or demount your "Jackhamers" and their range of work is thus greatly increased.

Bulletin 4046-c describes the entire "Jackhamer" family

11-Rand

Oil Engines **Condensers** **Vacuum Pumps**



Link-Belt Silent Chain Drives Used Exclusively

at Silver King Coalition Company, Park City, Utah

In rebuilding the mill, after the big fire of the Silver King Coalition Company, the type of power transmission in use was changed completely and Link-Belt Silent Chain Drives were installed *exclusively*.

Now, the Superintendent says: "I will never use any other form of drive but Link-Belt Silent Chain. It is unexcelled in all my experience."

Send for our Data Book No. 125. It is *not* a catalog but rather a handbook on silent chain practice. From it you can figure drives and determine prices. Return the coupon.

Ontario's Minerals

PROVINCE OF ONTARIO

Hon. CHARLES. McCREA, Minister. DEPARTMENT OF MINES *Thos. W. Gibson*

Mineral Areas

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favourable for the occurrence of minerals 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver veins of Cobalt, Gowganda and South Lorrain occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

Economic Minerals

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario: — actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluorspar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, Portland cement, brick and tile, meet every demand.

Mineral Production

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1922 to be worth $62,202,169, of which the metallic production was $38,190,711.

The following figures show the growth of Ontario's mineral industry by five-year periods since 1891 when a Bureau of Mines was first established.

Year.	Value.	Year.	Value.
1891	$4,705,672	1911	$41,976,797
1896	5,235,003	1916	65,303,822
1901	11,831,086	1918 (Maximum war output)	80,308,972
1906	22,388,383	1921	48,128,387

Dividends and bonuses paid to the end of 1922 amounted to $28,096,699 for gold mining companies, and $86,238,185 for silver mining companies or a total of $114,334,884.

Mining Regulations

A miner's license costs $5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of $2.50 or $3.00 per acre, depending on location in unsurveyed or surveyed territory.

Assay Office

The Provincial Assays Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

Publications

For list of publications, illustrated reports, geological maps and mining laws, apply to

Thos. W. Gibson,
Deputy Minister of Mines,

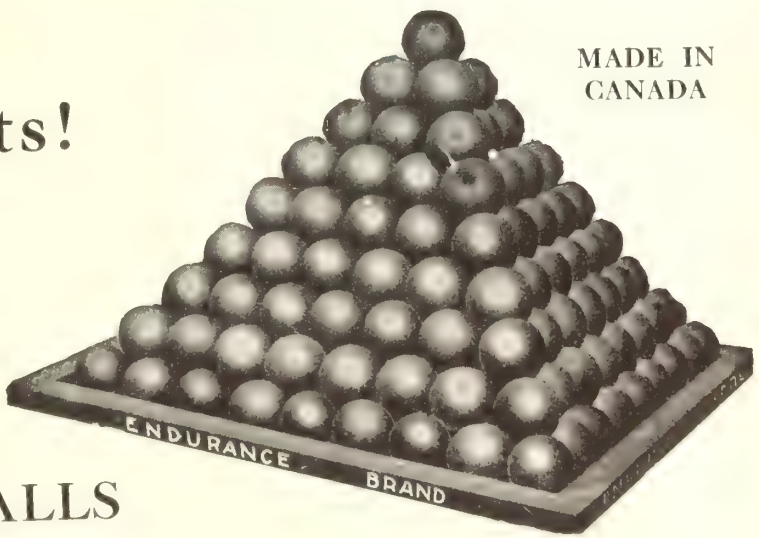
Cut Your Grinding Costs!

Nothing adds to the cost of grinding operations like faulty grinding balls.

Nothing will reduce your grinding costs like the tried and dependable

MADE IN CANADA



INDURANCE FORGED STEEL BALLS

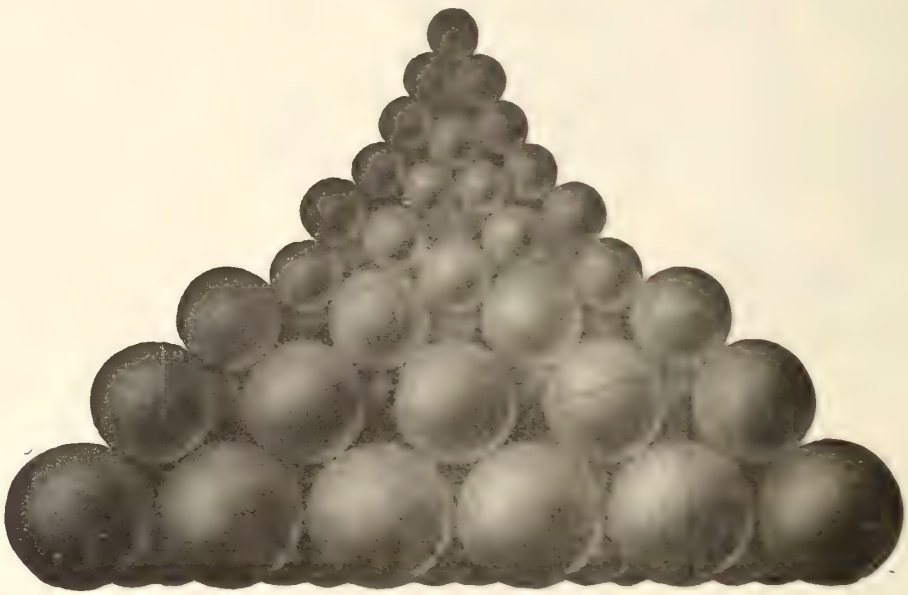
The reputation these Balls enjoy for all round satisfactory and economical service is the surest measure of their real worth.

Prompt shipments.

CANADA FOUNDRIES & FORGINGS, Limited

WELLAND, Ont.

Decrease your grinding costs.



USE HISCO BALLS

"If quality counts use 'Hisco' Products" *Hisco Balls* are noted for superior quality. They are in use in the largest ore and cement mills from Halifax to Vancouver. Forged from Electric Furnace chrome steel, absolutely the best ball on the market.

Sizes 3, 4, 5 and 6 inch carried in stock.
Special sizes from 6 inch up made to order.

Serving Canada's Mining Industry

It is many years since The Imperial Bank of Canada, recognizing the importance of the Canadian Mining Industry and realizing the need of banking facilities for those engaged in its development, first opened a branch in Northern Ontario.

Since then the Imperial Bank's service has gradually extended until the mining interests in the rich area between North Bay and Hearst are now linked up by a complete chain of 12 branches.

This Bank's service to the mining industry is not confined to Northern Ontario alone. In all the mining areas throughout Canada the "Imperial" is rendering a valuable and complete financial service.

LAKE FORTUNE AND NORANDA

The work of prospecting and development in the gold district of northwestern Quebec during the season now drawing to a close has been productive of highly satisfactory results. The faith of the handful of men who have persisted in their search in spite of discouragement has been more than justified. Unless evidence obtainable at the surface should be belied by underground development, Quebec has now in sight two substantial gold mines, with more to follow.

On another page there is described the property of the Lake Fortune Mining Company. The examination of the surface showings has of necessity remained incomplete; but the operators, who are men of wide experience in preliminary mining development, are so confident of what underground exploration will disclose that they have committed themselves to an extensive programme. Twenty-five tons of camp supplies are now on the way to Lake Fortune by canoe. Mining equipment is already on the ground. Within a couple of weeks mining operations will be under way. Before next spring the nature of the ore-body at the 200-foot level will have been at least partially disclosed. A mill is ready to operate as soon as the development of ore shall have justified it.

Twelve miles to the east of Lake Fortune, on the property of Noranda Mines in Rouyn township, intensive prospecting has disclosed what is, judging by all evidence available so far, a phenomenal body of gold ore. In a recent communication to shareholders, the managing directors, Messrs. Thompson and Chadbourne, announced the discovery on the most southerly of their group of claims of a mineralized zone carrying good values over a width of ninety feet, and high values across lesser widths. At that time there were two trenches across the ore-body. Last week there were a dozen or more such trenches, and these confirmed the hopes based on what the first disclosed.

The ore is an altered rhyolite, impregnated with pyrite and quartz, and containing as well rusty-weathering carbonates, tourmaline and galena. Gold is visible in many places. A large part of the low-lying ridge showing above the mantle of clay that covers most of the ground is composed of this gold-bearing material. Weathering has reduced it to gossan, and it is necessary to dig and blast through this in order to determine the original nature of the ore and to sample it fairly. The length of the gold-bearing zone as determined by these trenches up to last week was approximately 600 feet, and its width, over 300 feet. It remains to be determined how much of this constitutes ore of milling grade.

A thorough examination of the original vein of the Noranda property upon which such high hopes were built last winter was distinctly disappointing, and it appeared a few weeks ago as if the property would have to be abandoned. Now some intensive prospecting performed on outlying claims in the performance of assessment duties has changed failure into success. A diamond-drill and a small mining plant are already on the ground, and both will be put to work on the new discovery. The difficulty of summer travel into the heart of Rouyn township will, unfortunately, impede the delivery of supplies and machinery at the Noranda camp; but once the snow comes an excellent winter road from the railway will speed up operations. If half the promise of this new Noranda outcrop is fulfilled, Quebec will have a gold mine of world-wide repute.

Meantime prospecting of the intensive variety has had very satisfactory results in two additional widely separated localities, one in Rouyn township and the other in Dasserat township within a comparatively few miles of the Ontario boundary. It is still too early to disclose the exact location of these discoveries or to attempt to gauge their ultimate value; but the owners, who are experienced engineers and well able to judge, have prepared to investigate thoroughly the first promising showings.

Summing up the evidence at present available, it seems that the first full season's work in the new goldfield of Quebec has justified our early hopes, and that productive mines will be operated in the near future in the western part of the belt. We hope we shall be able to say the same of the eastern section before the season is through.

ANOTHER ATTACK ON THE PROSPECTOR

The *Canadian Forestry Magazine*, now known as *Illustrated Canadian Forest and Outdoors*, persists in its calumny of the prospector as a fire-bug. Half its editorial space in the September issue is devoted to the question, "Grub-Stakers or Tall Timbers?" We have already shown in these pages that, although we deplore the prevalence of forest fires and stand ready to condemn the carelessness of all who set them, yet we are not prepared to accept the estimate of the *Canadian Forestry Magazine* and other equally ill-inform

ed as to the comparative measure of the prospector's guilt. The editorial in question cites three fires. About the first we have no information. The second one mentioned is known to have been set by a fire ranger. The third one, on the road to the Rouyn gold area, we crossed three weeks ago, and found on inquiry that it had been started by road-builders working for the Department of Colonization of Quebec. We know, on the other hand, of a fire during the present season that was set by prospectors; but the damage it did was of comparatively limited extent.

If those who talk and write thus loosely about the prospector's predominant responsibility in the destruction of our forests by fire, will take the trouble to learn the facts, they will moderate considerably their present attitude. From first-hand knowledge we know that prospectors in general are not guilty. We have taken pains to trace to their source recently a number of fires, and in all but the one instance mentioned, the lumberman, the settler or the road-builder has been that source. Let us be fair to the prospector.

"UNDISCOVERED MINES"

A paper is to be presented by Dr. W. L. Uglow at the Trail meeting of the Canadian Institute of Mining and Metallurgy on October 17th in which he deals with the problems of mine discovery, and discusses in a constructive way the means by which it may be assisted. It is published in the October issue of the *Bulletin* of the Institute.

Not long ago, the question was asked by the head of a Canadian Government Department. "Why it is that capitalists do not seen anxious to acquire prospects in Canada?" The want of understanding implied by this question is reflected also in the attitude of owners of prospects in the valuing of their properties.

The fact is that the attraction of a prospect depends as much upon the external conditions with which it is associated as upon its own intrinsic potentialities. There is always an inherent attraction in prospects, as there is in everything connected with a risk; it is the very human attraction toward gambling,—taking chances. One hears of the gambling fever; it is a very apt term; no fever is constant for long, and the gambling spirit has its ups and downs in the same way. The present is not a day of high-temperature gambling, of winning or losing on a throw, or of thousand-to-one chances, or having all one's eggs in one basket. It is a day of more cautious procedure, and of reasonable risks.

The risks of mining are notorious. Chiefly they are connected with the hazards of exploration and development. One has to be prepared for many disappointments in the hunt for a mine. Dr. L. C. Graton's parable of the battleship is pertinent. He says: "Suppose a new battleship goes to sea to try her big guns at target practice. The explosive and projectile for each shot cost $250. Assume the Navy average for vessels of that class is nine shots to one hit, and that our particular ship sustains that average. Here, on the deck, lie nine projectiles; one will hit the target, yet no one can tell which one, for they all look alike. The nine shots are fired; one hits; that one represents an expense of $250, yet it really cost $2,250 to hit the target once. A prize of $1,500 offered by the company that built the ship, if the crew would equal the Navy average of one hit in nine shots, might seem to yield a handsome return if one thinks only of the single shot that reached the mark; but in reality, the prize, instead of affording a surplus, leaves a deficit."

Dr. Graton also cites an instance of a company in South America that investigated 143 prospects in order to find one mine. Admitting that such pertinacity is unusual, one has to admit that the number of unprofitable investigations is likely to be large before a winner is found. This fact constitutes the principal hazard in mining, and it is clear that it may be immensely aggravated by injudicious methods of selection.

A poultry breeder recognizes a certain risk-factor in the matter of incubation, but it would be seriously affected if he bought cold-storage eggs to experiment with. In the same way, an investor wants to know how many chances he has of finding a mine in a new field, before he will wax enthusiastic about it. A one-mine field is bad enough, but a one-prospect country leaves the investor cold.

It is the country that requires to be known first, and the opportunities that it offers for the discovery of mines. If the chances of success are reasonable, there are plenty of people ready to risk their money in it, to whom appeal may be made in vain on behalf of individual prospects. This is a reasonable attitude, irksome though it may seem to the optimistic prospector or promoter, and it calls for practical steps by which an estimate may be made of the country's possibilities, by which means the investor may be provided with a gauge to estimate his risk, whether he requires a ten-to-one, a fifty-to-one or a 143-to-1 chance.

What sort of a chance, for example, is that presented just now in British Columbia? Is it to be measured by past records, or can these be bettered? The record can undoubtedly be improved, since the element of chance in mining everywhere can be reduced by the adoption of scientific methods in prospecting and investigation. Herein lies the route for the Province's waning activities in prospecting. When we are worried by symptoms of its lack of vitality, we should ask ourselves not "what is the matter with the country", but "what is the matter with us". Dr. Uglow's argument is to show that British Columbia is a field that can be made to attract capital, and he shows us how to go about it.

MR. ROBB AND IMMIGRATION

The Hon. J. A. Robb, recently appointed Minister of Immigration and Colonization, has issued a statement outlining a new policy of immigration. And we believe that its whole-hearted adoption and prosecution would help very largely to augment the tide of immigration to these shores. In such very largely augmented volume of immigration is to be found the solution — or, at any rate, a large part of the solution — of nearly all of our most pressing national problems, including the most pressing of all, that of the Canadian National Railways.

So far as it is possible, we are most solicitous that this augmented immigration should come from Great Britain. The Dominion Government, some time ago, formulated certain plans for obtaining immigration from this source. But, as we took occasion to point out at the time, these plans of the Government did not go far enough and showed scant likelihood of adding very largely, in the near future, to the number of producers in this country. In fact, we have never been able to regard them as, in any sense, adequate to the imperative exigencies of the circumstances in which Canada finds herself. Mr. Robb now announces that "in co-operation with the British Government, under the terms of the Empire Settlement Act, it is proposed to extend the schemes affording assistance to those of the agricultural and home-worker classes from the Mother Country." This announcement may mean much or little—let us hope it means much.

For our part, however, we have always recognized that, even at the best, all Canada's immigration needs cannot be supplied by the Mother Country. For one thing, we need more than the latter can furnish of the right stamp. For another, there are certain classes of rough work for which immigrants from the more Southern of European countries seem better suited. All such industrious European settlers as are capable of being transformed into Canadian citizens should be made welcome in the interests of the Dominion at large. In this connection, we are confident, subject to the proviso in our next sentence, that, in announcing that "as the British Isles alone cannot furnish a sufficient quota of the agricultural classes, efforts will be made to encourage immigration from certain areas of the continent of Europe and from the United States," Mr. Robb is proposing to proceed along sound lines. That is, always provided that it is regarded as essential, that, if settlers are brought to Canada from certain of the Southern European countries, they should be carefully hand-picked in Europe. For there is a danger — and this fact has been impressed on Canadians during the late war — in bringing to this country, in any really large numbers, aliens who are resolved not to be absorbed and assimilated, but rather to form colonies of their own and adhere to alien mental and political standards. Great care is needful in their selection.

It is announced that "facilities will be offered for the immigration of such skilled and unskilled labor (other than agricultural) as Canada may require from time to time." With this we are in hearty accord. We believe that it is necessary to open the doors wide if we are to bring to this country such a volume of immigration as will both substantially increase production and add to the wealth of the Dominion. We want to see the doors opened not only to farmers and farm laborers, but also to such an extent in other directions as will enable our manufacturers and business men to secure the skilled workers and other help they require in their industries. At present, they cannot get these. Nor will they easily be able to do so, if the Labor unions in this country can work their sweet will. We have a shrewd idea that it is the fear of offending these Labor unions that has been responsible for the lethargy and laxity that the Government has so long displayed in this matter of immigration.

As we have said, we are generally in agreement with Mr. Robb's enunciation of the new immigration policy. But, after all, "fine words butter no parsnips." The Government will be judged by deeds, not words. It has hitherto been so slack and procrastinating with regard to this question, all-important as it is, that one may well be pardoned for not being ultra-sanguine as to its policy being now inspired by a new spirit.

A FOOL AND HIS MONEY —

Here is an interesting letter from one of the *Journal*'s readers:

"A man whose business experience has been successful and honourable called on me the other day to ask for a suitable investment in mining for a considerable sum of money. When told that the approximate cost of investigating the merits of a certain mining undertaking known to be in need of additional capital would be about 2½ per cent. of the proposed investment, he hastily replied, — 'Oh, I never heard 'of that being done in a mining matter. But if you ' know of a chance that you consider good, I should be ' glad to get into it without any expense of that kind.'

"Now this man has been a banker and a broker. He was in earnest, and I do not think he had any thought of being what he actually was on this occasion,—a mere 'piker'. He knew that securities offered by reliable underwriters are first carefully investigated from both the physical and the financial sides of the proposal. But a mining proposition he regarded as something that might as well be estimated by hearsay.

"Can't you write something in the *Journal* to enlighten this poor cuss, and others like him?"

Our correspondent has put the case so succinctly that we can add nothing to his exposition of the case. Nevertheless we should be glad to have the views of [illegible]

Lake Fortune Gold

Description of Promising Property in Northwestern Quebec

By THE EDITOR

The gold belt of northwestern Quebec is now known to contain more than one deposit of gold whose outcrops rank with the best, and whose development promises to make mines of some importance. Among these the Lake Fortune Mining Company's property is outstanding. I visited it in the middle of September, and learned at first hand the following facts:

Location and Communications

Lake Fortune is on the gold belt that extends eastward from Matachewan and Kirkland Lake in Ontario for 100 miles into Quebec. It is ten miles east of the inter-provincial boundary, astride the Dasserat-Boischatel township boundary. A good winter road connects it with Dane station on the T. & N. O. Railway, and from Lake Fortune to Larder Lake this road is used as a trail, 14 miles long, in summer. It is 45 miles south of La Sarre, on the Canadian National Railways (Transcontinental line), with which it is connected by an excellent and direct canoe route. Forty-five miles to the south is the Quinze River. Lac Des Quinze, Barriere Lake and Opasatika Lake form a waterway from the Quinze water storage dam to the north end of Opasatika Lake, which is 2½ miles by road from the Lake Fortune camps. This route is navigable throughout by small steamers except for a 1,000-foot portage between Barriere and Des Quinze Lakes.

Within a few weeks the Kipawa extension of the C. P. R. will be in operation to the Quinze dam, whence the water route northward, approximately 50 miles in total length, is available as mentioned above. The Larder Lake branch from Swastika on the T. & N. O. is now under construction as far as the two gold properties of Crown Reserve and Associated Goldfields north of Larder Lake, which will bring the steel to within 17 miles of Lake Fortune; but the interprovincial boundary intervenes.

Roads and Agricultural Land

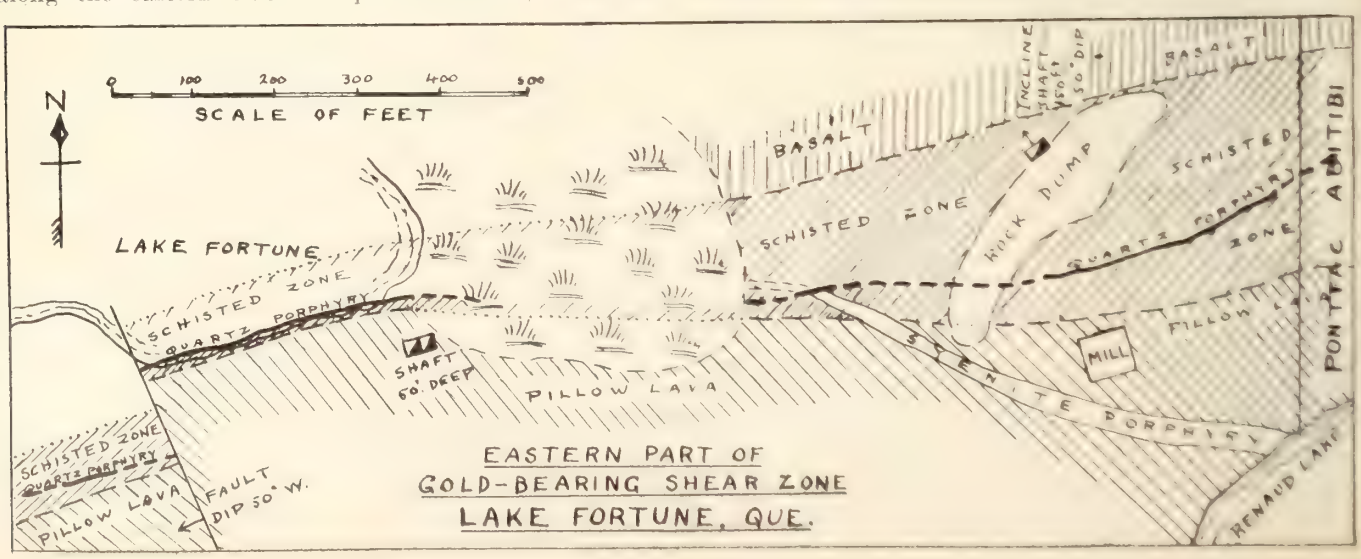
Lake Fortune is near the southern edge of the Great Clay Belt, and a number of colonization roads are being pushed forward in its direction. The southerly extension or lobe of clay land that includes New Liskeard and Ville Marie extends northward without interruption along the eastern side of Opasatika Lake, from Des Quinze river. A colonization road extends from North Temiskaming at the mouth of Des Quinze, about halfway to the southern end of Opasatika Lake, a total distance of 25 miles, all through good agricultural land. Last spring the Quebec Government made a grant of $15,000 towards the completion of this road. This sum has been expended mainly in re-location and clearing a part of the new road. It is expected the grant will be renewed, on a more adequate scale, during the coming year.

Settlement along the Transcontinental line on the Quebec side of the boundary has proceeded with remarkable rapidity since it commenced in earnest in 1917. A strip of approximately 10 miles in width along each side of the railway is now settled for a hundred miles eastward and roads constructed for this distance. Those from La Sarre and Makamik are already within 30 miles of Lake Fortune and are being pushed forward steadily with the settlement. Either could be built through to Lake Fortune to advantage, as the good agricultural land extends throughout the whole distance.

It may be noticed in passing that the 100-mile gold belt lies approximately along the southern edge of the Great Clay Belt. The area of the section of the clay belt between it, the Canadian National railway and the interprovincial boundary is somewhat greater than that of the Eastern Townships of Quebec, while the proportion of arable land is much greater. This intimate relation of prospective mines and agricultural land in such large amount is of prime importance to the province.

General Geology

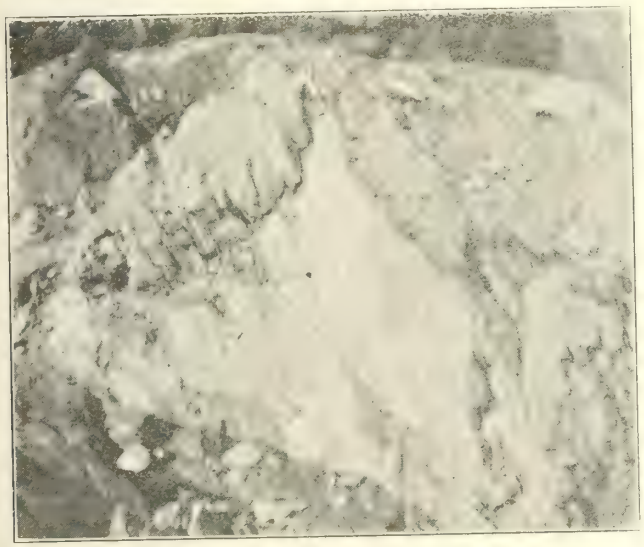
The geology of the area is described by M. E. Wilson (G.S.C. Memoir 39) and by H. C. Cooke (G.S.C. Summary Report 1922, Part D.) The gold occurs in this case, as in numerous others, in lava flows of Keewatin age, not far from their contact with superimposed conglomerate of the Temiskaming series, the bedding planes of both being now in an approximately vertical position. At a distance of ten miles or more to the south, and also presumably underlying the older rocks, is the great granite batholith. A later intrusive, which is considered to have brought in the gold, is in evidence as dykes and bosses of acidic porphyries.



South of Lake Fortune is a strip of sedimentary rock of the Cobalt series, which overlies and conceals the contact of the Keewatin volcanics and the Temiskaming conglomerate. To the southeast at a distance of about a mile this Cobalt conglomerate has been eroded sufficiently to expose a large intrusion of syenite porphyry intruding Temiskaming conglomerate.

Geology of the Ore Deposit

The principal geological features of the Lake Fortune property is a shear zone, indicated by Cooke on his



Lake Fortune Ore
Schist with stringers and irregular masses of quartz. The ore in places resembles closely some of that of the Porcupine camp, particularly that of Hollinger. Hammer shows strike and dip of schist.

map as a fault running east and west for a distance of over a mile. The company's property covers three-quarters of a mile of this zone, one-half mile of it east of the Boischatel-Dasserat boundary and one quarter to the west. The zone has been explored partially on the surface for a distance of 1,500 feet from the eastern boundary. Little or nothing is known at present of the remaining 2,500 feet. Indeed, only a beginning has been made in examining the eastern part; but this has disclosed several features of geological interest.

The shear zone is in lava of Keewatin age, and consists essentially of schisted lava. On the south the rock is principally lava with "pillow" structure. On the north side basalt is the principal rock. The zone conforms roughly with the bedding planes of the lava. It dips at 50 degrees to the north, and is from 80 ft. to 350 ft. wide, as so far determined.

A dyke of syenite porphyry cuts the pillow lava and the schisted zone, as indicated on the accompanying sketch plan. There is no indication as yet that this dyke is connected directly with the gold deposits it is hoped to mine profitably.

A narrow dyke of quartz porphyry, up to about four feet in width, extends irregularly throughout the shear zone so far as examined. It cuts the syenite porphyry dyke. Most of the shoots and pockets of high-grade gold ore so far discovered occur in intimate contact with this dyke of quartz porphyry.

A fault with a lateral displacement of 130 feet and a dip of 50 degrees to the west intersects the shear zone as indicated on the plan. High-grade ore has been found in this fault. The lateral and vertical extent of this ore have not been determined.

Mineral of the Shear Zone

The schist of the shear zone is intersected by a multitude of veins, veinlets and irregular small masses of quartz, distributed unevenly throughout the zone. There is a similarly uneven distribution of pyrite throughout the schist, mostly as small crystals. In places this pyrite constitutes the major part of the rock material, but only in very restricted areas.

Where the foot-wall of the schisted zone appears along the shore of Lake Fortune, molybdenite is distinctly in evidence, in conjunction with high gold values, alongside the quartz porphyry dyke.

Though there have been some spectacular nuggets of gold found in the quartz and the schist, these occurrences are rare. Most of the gold is in a finely divided state and is separated readily from the rock by panning after crushing to a moderate degree of fineness. The evidence available so far goes to show that simple amalgamation will recover most of the gold.

Panning shows that there is gold everywhere throughout the schisted zone. Both panning and the assays of channeled samples show, however, that these values, probably the result of the first deposition of gold in the zone, are not workable except where concentrated. The evidence available to date indicates also that the gold values are mostly in the quartz and the schist. It is not known as yet what proportion is in the pyrite.

Payable Ore

When the present examination of the Lake Fortune property was begun last May by Messrs. Alderson and MacKay, the work on the ground consisted of two shafts, one south of the schisted zone and the other on its northern edge or hanging wall, and a number of small pits on outcrops. Today trenches cross the zone in places where the overburden allows, channel samples have been taken along these trenches and in the old pits, and the shoot of high-grade ore along the shore of Lake Fortune has been stripped. At present an

Outcrop of schist cut by quartz stringers, of the incline shaft. High gold values and spectacular samples have been found at this spot.

attempt is under way to lower the water of the lake by deepening the outlet, in order to allow systematic sampling across this ore-shoot. In the meantime the values disclosed by panning and by the assays of such samples as it has been possible to take along this enriched zone virtually compel vigorous development.

As noted above, most of the high-grade ore so far discovered occurs along the quartz porphyry dyke. On the shore of Lake Fortune it runs close to the foot-wall of the shear zone, and is divided into two or three parallel small dykes. Alongside these little dykes there is ore of remarkable richness, extending for a length of

about 200 feet and with a total width of four to six feet. Owing to there being only a narrow strip either above water or within arm's length under water, the width can be determined definitely only by exploration underground. Meantime a stoping width of about five feet of rich ore is indicated. It is not known at present how far the high values will extend beyond this width.

At a number of other places where it has been possible to examine the schist along the quartz porphyry dyke, spectacular specimens and high assay values have been found. Up to the present, these values have proved to be somewhat erratic, and no continuous body of high-grade ore has been delineated with the exception of that along the lake shore. It must not be assumed, however, that there are no other ore-shoots, for the amount of this preliminary surface exploration has been so small and it has been scattered along such a length that it can be counted only as a beginning. For instance, all the present information points to the foot-wall of the zone as the best prospecting ground; but this is so deeply

Channel sampling across the shear zone hammer shows strike and dip of schist.

covered with drift that it can be examined only along the edge of Lake Fortune, where the first ore-shoot is indicated.

Projected Development

The new owners of the Lake Fortune property have determined to "follow the gold" — a good rule in any case. Before exploring at large throughout the schisted zone, they will determine the extent and value of their first ore-shoot. Hemmed in by the lake to the north and by a swamp to the east, the possibilities of surface examination already have been almost exhausted. An old vertical shaft 50 feet deep will aid in underground exploration. This will be continued to 100 feet or more in depth. A cross-cut of slightly less length driven to the north should intersect the foot-wall of the ore body under the end of Lake Fortune, whence exploration drifts in any direction can be run at will. There is already a drift from the bottom of the 50-foot shaft northward for 20 feet—too short a distance to reach the foot-wall—but this will not be driven further. This underground prospecting will be the surest and cheapest means of investigating the ore-body further.

The shaft to the east is an incline at 50 degrees in the hanging wall of the shear zone, 150 feet deep. From the bottom a drift was run northward into the basa't for 400 feet, presumably in an attempt to reach a quartz vein in that direction. Another drift was run for a short distance southwest into the schist. It is not known what values this latter disclosed.

Mining Equipment and Mill Already on the Ground

All the equipment required for mining on a small scale is on the ground and in good condition, having been installed by former owners. In addition there is a small mill, which can be put into commission at small expense. It is not quite finished. A saw-mill is ready to operate. Steam engines run an electric generator for lighting and for mill motors, a two-drill air compressor and the saw-mill.

The mill is solidly constructed on a hill-side. A 12" by 15" jaw crusher discharges to ore-bins which feed to four heavy Tremaine stamps. These discharge to amalgamating plates. Below are two Overstorm concentrating tables, which can be used to separate the sulphides if required. In addition there are two Frue vanners, which will not be useful. The estimated capacity of the mill is 30 tons a day or more. It can be used economically to treat high-grade ore.

Adjoining Properties

The schisted zone has not been prospected at all outside the property of the Lake Fortune Mining Company. To the east it extends onto the Pontiac Abitibi property. The western extension is covered by a claim staked recently by the Crown Reserve Mining Co., who also hold a claim to the north of the Pontiac-Abitibi. To the north is the King of the North claim, also unexplored. The area of syenite porphyry and Temiskaming conglomerate to the southeast is held by Redmond Quain and associates of Ottawa, who have at present a party stripping and sampling.

Operations Fully Financed

The operations of the Lake Fortune Mining Company are now controlled and directed by Messrs. Alderson and MacKay of Montreal. The former owners, Messrs. Bonner and Goyer and associates, retain a substantial share in the ownership. Sufficient money has been subscribed by Messrs. Alderson and MacKay and some friends to develop the property fully to the stage of adequate production, and to build a modern mill of such capacity as may be required. This money is already in the hands of the Company's treasurer.

Ore-shoot on the edge of Lake Fortune, looking east. Along the water's edge and under water $200 ore is found. Shovel indicates dip of schist.

Mr. MacKay was at the property at the time of my visit. I wish to acknowledge gratefully his courtesy. The facts cited above are mainly what he has determined and the geological deductions with regard to the occurrence of the ore are his. Both he and Mr. Alderson are experienced and successful mine operators, and both have in unusual measure the rarer quality required for prospecting and preliminary development. They have the hearty support of the former owners, who remain their associates and will share the results of development. They are associated with a financial group well acquain-

tomed to mining investment and both able and willing to provide all the funds that may be required.

Now it is up to the property to make good. At present it is a prospect of unusual promise. Should that promise be fulfilled even in small measure, Quebec's first gold mine will be established. If a half of what is promised by the outcrop should be realized, that mine will be a big one. By this time next year these questions will be at least partly resolved.

PLATINUM SWINDLERS OPERATING IN CANADA

Reports of the finding of platinum in many of the mining districts of the United States have been creating a stir in "get-rich-quick" circles of the West. The discoveries, according to these accounts, are particularly rich in the States of Idaho and Washington. The value per ton of the ore on the dump, in the case of a Company with headquarters at Seattle, is something fabulous, according to the statements of promoters. A Victoria resident, who has been identified with the mining business for years, has been generously offered the chance of "getting in" in the ground floor for a mere $50,000; but he must act before the mill begins to grind out the wealth that is "on the dump." The gentleman who was asked to invest felt that he would have to receive more information before acting, and applied to the B. C. Bureau of Mines. He was shown recently published reports of the United States Bureau of Mines and the Bureau of the State of Idaho. Then it developed that many mining properties, publicly advertised as producers of platinum and the metals of the platinum family, had been investigated by the authorized officials of the United States Bureau of Mines and that the assay returns obtained by that Bureau have been negative.

It would appear, therefore, that the "game" which has been and possibly still is being played on the other side of the line is likely to be tried in Canada. The condition has been grappled with by the United States Bureau of Mines most energetically and effectively. Their representatives secured the samples and the assays of 44 ores which were represented by the promoters as containing platinum. These samples the U. S. Bureau of Mines had assayed carefully, but in no case did they find any platinum. These results they published side by side with the names and extravagant claims of the promoters. Thus one reads of a property, the subject of a prospectus claiming to contain ore running anywhere from 200 to 300 oz. of platinum to the ton, with the word "none" under the "platinum content" column of the U. S. Bureau of Mines Report.

In the face of this public exposure it might be thought difficult for the successful delusion of the public to continue. It is more than likely, however, that the official reports of the Mining Bureau of the States do not get the general publicity that their importance warrants, just as the reports of the Canadian Geological Survey of Canada, many of them of absorbing interest, do not reach the hands of all who might like to have them if they knew of their existence. Canadians, however, have much to be thankful for in the present instance, because the United States' Mining Bureau has given the warning, and has supplied the material that will effectively "kill" any effort to sell stock (or "units" as the promoters prefer to call them) in these fraudulent platinum flotations.

This serves to recall an episode in the mining history of British Columbia. It was in 1911 and 1912 that platinum was reported to have been struck on mining properties in the Nelson District. Excitement resulted. Many claims were staked and companies were proceeding to find the funds needed for the erection of mills for the extraction of the precious metal. A. G. French started the ball rolling when he announced having found platinum and metals of the platinum group in certain dykes in the vicinity of Nelson and notably in dykes of the Granite-Poorman Mine. He said also that he had evolved a process by which they could be economically extracted.

Wm. Fleet Robertson, Provincial Mineralogist, was called upon to investigate these claims and deals with them in the Annual Report of the Minister of Mines, 1912, outlining the circumstances above narrated, and detailing the steps taken by the Provincial Bureau of Mines to either prove or disprove the claims made by Mr. French Samples were obtained and forwarded to the leading metallurgical chemists of America and England. In all cases the results showed platinum "nil." The mining flurry, based on the assumed existence of platinum, passed away. It was unfortunate that it occurred at all, as there is no doubt that the district suffered the inevitable reaction. This, however, is casting no slur from the viewpoint of mining on the highly mineralized section of which Nelson is the centre. The developments of the past few years speak for themselves. No part of the Kootenays, least of all the Nelson district, needs spurious boosting to assist it to mining prosperity.

PERSONAL AND GENERAL

Mr. Minor C. Keith, of New York, who is interested in the Premier Gold Mining Co., has returned after a visit to the Premier Mine. He was accompanied by Mr. H. C. Price, consulting engineer. Mr. Keith is quoted as saying that the new tunnel of the Premier has passed the 600-foot mark, that it will be double-tracked, and that the new 1,000-ton mill will be constructed at its portal. Mr. Keith seems much pleased with the conditions and the future prospects of the camp.

Dean R. W. Brock was Canada's representative at the Pan-Pacific Science Congress held in Australia recently. He and other delegates inspected the Broken Hill and other mines in Australia and Tasmania.

Prof. H. E. T. Haultain has returned to his duties at University of Toronto after a few weeks in the Porcupine district.

Mr. W. R. Tonkin, mining engineer of Seattle, who formerly was interested in the Fish Creek Mine now owned by the American Mining & Milling Co., has returned south after some months in the Portland Canal District. He is one of the owners of the Bear River Group of claims. Mr. Tonkin states that the season now closing has been one of the most active in mining ever seen in the British Columbia northland and that the future of the Salmon and Bear River areas is assured.

Mr. G. B. D. Turner, managing director of the Indian Mines Ltd., has returned to Stewart and will spend the rest of the season at the mine.

NICKEL IN SPITZBERGEN

Nickel is reported to have been discovered in Spitzbergen. Mr. Carl Sjeber [illegible] to Trondhjem, Sweden, after a season's exploration in the islands. He has made no public statement of the size of the deposits or their exact location.

The man who wrote most wisely, said,
"Be sure you're right, then go ahead."
Might well have added [illegible]
"Be sure you're wrong before you quit." —Ex.

An Iron and Steel Industry for British Columbia

Victoria Chamber of Commerce Shows That Proposals of Coast Range Steel Company are Unsound, and Indicates a Probable Rational Solution

The Coast Range Steel Company Limited has been organized for the establishment of the iron and steel industry in British Columbia. Its chief promoter and the most ardent exponent of its cause is Mr. H. J. Landahl, who has worked on its behalf in London, Ottawa, Victoria and Vancouver. Recently he and his associates have been particularly active in British Columbia. They have obtained, through well directed and insistent effort, the support of most of the public bodies of the chief cities of British Columbia. One organization, however, has declined to back Mr. Landahl, viz., the Victoria Chamber of Commerce. This decision was reached, it is said, after careful consideration by a special committee. The report of this special committee has been published and is of interest because it differs so materially from the views publicly expressed in this Province on the question.

Following is the full text of the report:—

"Your committee, instructed by the president to investigate and report upon the projected enterprise of the Coast Range Steel Company, wishes to state as follows,

"The Coast Range Steel Company, promoted by H. J. Landahl, has for its object the establishment of a complete iron and steel plant at a cost of $15,000,000.

"The financial proposals are that the bonds of this company be guaranteed as to a one-third interest each by the Imperial Government, the Dominion Government and the Provincial Government. A propaganda seeking, and so far obtaining, the endorsation of various public bodies, particularly the boards of trade of this Province, has been carried on to press upon the Provincial Government the granting of the necessary bond guarantees, and the statement has been freely made that both the Imperial and Federal Governments have consented to contribute their share of guarantees. We have it on excellent authority that these statements are not in accordance with the facts.

"The Imperial Government has stated that it is prepared to consider guaranteeing one-third of the bonds, provided this guarantee shall be considered as a first mortgage on the entire properties and that any guarantees for the balance of the bonds both from the Federal and Provincial Governments shall be subservient to its own first charge.

"We learn from the officials of the Canadian Manufacturers' Association that the Dominion Government has stated positively that it is not prepared to guarantee any bonds issued for this enterprise, so that the entire financial burden would fall upon the Provincial Government. If it were possible to see any chance of such a venture becoming successful, it might be worth the most careful consideration, but in view of the actual facts, which apparently have not been ascertained by those whose money would be involved, namely the people of this Province, and in view of the facts set forth herein, we submit that our Chamber of Commerce should go on record as being entirely opposed to the proposition as set forth by the promoters of the Coast Range Steel Company.

"This particular proposal or scheme, in our opinion, should be condemned for the following reasons:

"It would appear from our information that the proposition is that, apart from the guarantees of the bonds which would be sold to erect the plant, common stock should be issued for the absorption of alleged iron ore properties and for properties containing the other raw materials which would enter into the production of the finished article. The affairs of the Company would be in charge of holders of the common stock, and there has been no suggestion of any security to prevent the paying of prices for these raw materials which would preclude any possibility of covering the overhead interest charge. It is represented to us that the quality of the coke produced on this coast is such as to make the profitable production of pig iron by the blast furnace process a matter of grave doubt as to its commercial practicability. The propaganda of the company does not show any estimate of the cost of the steel plant, including blast furnaces with blowing engines, ore yards, power plants, coke ovens with the facilities for producing by-products, blooming mills, billet mills, and finishing mills, together with all the subsidiary plants which would be required to produce such items as wire products, bolts, nuts, pipe, tacks, screws, etc., all of which must be contemplated by Mr. Landahl in view of the high capitalization of his company. It should be pointed out that plates, bars and structural material can be landed in British Columbia to-day, duty paid, from Belgium, at practically as low a cost as the selling prices at the mills in Montreal or Hamilton.

"The pig iron consumption in British Columbia is so limited that a plant such as proposed could take care of a year's consumption in less than one month's operation per annum, and the one essential to the profitable operation of a steel plant is volume of output. It has been stated to the Government that a large market is offering for British Columbia pig iron in California. Upon investigation it is stated that if the quality produced is equal to or better than that now obtained, and if the material could be sold to them in California at a price which they would deem satisfactory and which, in other words, would be lower than they are now getting, then they could use several thousand tons per month. We think the provisos would eliminate the possibility of obtaining a market in that state against such competition as the United States Steel Corporation, running its own boats from Birmingham, Alabama, to San Francisco, would provide, which would most certainly not be willing to forego its home market.

"The steel rail business in Canada is taken care of by the Dominion Iron and Steel Company and the Algoma Steel Corporation, which, by operating for short periods off and on during the year, are able to supply the entire Canadian market. The whole gross business of the Dominion of Canada is not big enough to take care of the supply of one sheet and plate milll, and the Dominion Iron and Steel Company, which built a plate mill some years ago under a Dominion Government bonus with a guarantee as to tonnage and price, has dismantled its plant and accepted $4,000,000 from the Government treasury to cancel the contract.

"The British Empire Steel Corporation, embodying the Dominion Iron and Steel Company, the Nova Scotia Steel and Iron Company and other plants, situated most advantageously for both the home market and export business, owning its own steamships and railways, has not been able to make a profit on its investment.

"The demand for the whole Dominion on structural steel and shapes has not been sufficient to warrant the es-

tablishment of a plant for this material in the Dominion, and none exists today. The tremendous variety of sizes and shapes and the capital investment required for the manifold number of rolls requiring to be changed constantly to meet the call for various shapes, demands such an investment of capital as the business of the Dominion has never yet warranted. Every successful industry has had to be built up upon its home market, and the market in British Columbia could be taken care of by such a plant in a few weeks' operation per year. The export business of finished steel product is always precarious. We could not hope to compete with Eastern Canada for markets east of Alberta, with our costs of transportation and production; and on sea-borne export trade we would have to compete with the ironmasters of Great Britain, with those of the United States owning and operating their own boats, and with Belgian material, which, as stated above, can be delivered at our doors at lower prices than the material could be produced for here or anywhere else in Canada. We understand that the Canadian Manufacturers' Association has made an investigation of this steel project and condemned it unequivocally.

"We are of the opinion that it would be greatly to the interests of this Province, however, if some means could be devised whereby production of pig iron on a small scale could be introduced, not necessarily as a profitable venture, but for the purpose of testing out the future possibilities in this direction. In this connection we may say that we are in touch with industrial parties at present located in the Province, who we beleive, have the facilities for doing work at small, if any, financial burden to the Government, and we propose to continue our negotiations in this direction in the hope of being able to submit to the Provincial Government at an early date some tangible suggestion in this regard.

"We have under consideration the utilization of some of our unused water power for the electro-metallurgic production of iron. We firmly believe in the great importance of our natural resources in iron and appreciate the effort of the Federal and Provincial authorities accurately to determine their character, extent and location. We hope that this work will be concluded as rapidly as possible and include a thorough investigation by special commission or otherwise, as these governments see fit, to advise as to the best way to bring these resources to account at the earliest possible date.

"We are of the opinion that economic conditions in British Columbia call imperatively for a greater use of our natural resources, of which iron is one of the most important. The successful production of pig iron in sufficient quantity and at a satisfactory price is the first step towards an iron industry, and from this initial step we may reasonably hope to see the following benefits accrue:

"1. The increase in number and kind of industries operating continuously, thus reducing the amount of seasonal unemployment.

"2. The attraction of a class of people to the Province for whom at present there is no opening.

"3. The retention of our young people in the Province by widening the scope of industry and multiplying the opportunities for employment."

Michael Faraday discovered the principle of the dynamo electric machine in the last century and without this knowledge, the whole art of electrical engineering could not exist. The value of electric power generated in Canada is $60,000,000 of which one-third is exported.

TOUGH-OAKES-BURNSIDE GOLD MINES

BY ALEXANDER GRAY

The Tough-Oakes-Burnside Gold Mines, Limited, capitalized at $5,000,000, will succeed Tough-Oakes Gold Mines, Limited, capitalized at $3,000,000. Judge F. H. Phippen of Toronto probably will be President; H. S. Denny, C. B. E. of London, will be Vice-President. Among the other directors will be A. Burt of London, England, and W. D. Wilson of Hamilton, Ontario. The par value of the shares is to be reduced from $5 to $1 and Canadians are to provide additional working capital. Of the $2,000,000 new capital, $1,000,000 will go to the Kirkland Lake Proprietary (1919) Limited, as the purchase price of three Burnside claims, held by Burnside Gold Mines, Limited. The other million will constitute the treasury. Not only are Canadians acquiring part of the treasury stock of the enlarged company, but they are taking options on some of the shareholdings of Kirkland Lake Proprietary (1919).

No doubt other details will be forthcoming shortly, as to the improved mining position at the Tough-Oakes and the possibilities of the Burnside areas. The more liquid situation to be created by the amalgamation, the share consideration conceded to the Kirkland Lake Proprietary, the participation of Canadians in what may be extricated from its embarrassments, will have more intelligent appreciation when the reports of the capable mining engineers in charge are made public. To justify the rearrangements and a market, the assumption is that enough encouragement has been met with underground at the properties involved to warrant optimism and increased activity.

It is entirely fitting to have the London interests in Kirkland Lake Proprietary effect closer contact with responsible Canadians. The success attending the Mining Corporation of Canada was attributable to the provision of "on-the-spot" administration. Otherwise the Townsite Mine of Cobalt might not so speedily have redeemed itself and been the basis of the merger of the Townsite, City of Cobalt, Lake and other properties. The Mining Corporation of Canada may be London-controlled, but it has a Canadian organization that commended itself to Canada and to international shareholders. A combination of London and Ontario capital, cicerone by Dr. J. Mackintosh Bell, brought the Keeley to the centre of the stage, where the spotlight does not detract from its charms.

Some of those who are not wholly blameless in the matter of the Tough-Oakes episode, now admit that a Canadian organization is essential. They sowed the wind and reaped the whirlwind, as it were. To liquidate certain outstanding obligations and to provide working capital for the Tough-Oakes, they had to sell their valuable interest in the Sylvanite. Thereby they enabled themselves to proceed to the exploration of the complicated Tough-Oakes faultings; but they had difficulty in finding enough ore to maintain the Tough Oakes on a continuous milling basis. Fortunately, however, the technical control and present executive at the mine have solved some of the besetting problems and the inference drawn from the creation of the new Tough-Oakes-Burnside Company is that now it has better prospects. London did not fare well with Tough-Oakes; Canada in co-operation with London may work to more profitable purpose. By bringing the Tough-Oakes Burnside back to the list of regular producers, Messrs. Denny and Thomas will render distinguished service to that section of Kirkland Lake

D. H. McDOUGALL'S RESIGNATION

There were heartfelt expressions of regret in the mining and steel producing districts of Nova Scotia when it was learned that D. H. McDougall, Vice-President of the British Empire Steel Corporation, had resigned. Sometime a prophet is *not* without honour in his own country and this is one of those rare occasions. Mr. McDougall grew up in Glace Bay among the working classes and though he far outstripped all his fellows in rising to positions of responsibility and trust, yet he never grew away from them. He remained one in sympathy with them, because he fully understood their aims and ideals in life. He passed through almost every phase of mining experience in his early years, after which he took up railway and engineering work.

When he attained to the second highest position in a great corporation he had helped to create, his fellow workers became justly proud of him. True, during most of the time since this corporation was formed, there have been acute labor troubles; but Mr. McDougall played a large part in helping to smooth them out. Now that "the winter of discontent is past," there is a warm feeling among all classes for Mr. McDougall, which is all the deeper because he was in the middle of the hurly-burly at its hottest.

In the recent labor crisis, the anxiety, and fear with which all looked forward to the final contest between Besco and its employees is still fresh in the minds of all. The confidence in the ability of Mr. McDougall to tide over the trouble, the tact with which it was done, and the short period of time in which the long drawn-out struggle was brought to a conclusion, have but accentuated his abilities. The peace that immediately followed and the rapid progress of the steel and coal trades have helped men to forget the bitterness of the past. Within two weeks, record outputs of coal were made, and these have been mounting higher since then. It seemed as if each district superintendent and mine manager had been waiting for the time to come when, untrammeled by labor troubles, unrestricted outputs could be given. Each vied with the other for first place. The No. 6 colliery district made the first large record, and was followed by Nos. 1 and 2, Nos. 11 and 24, and then Waterford. The increase for the month at Sydney Mines was more than 60 per cent above the best month of the year previous. Meanwhile the Acadia and Springhill Collieries, which had refused to come out on strike, were forging ahead and keeping pace with all others. The strike ended in the last week of July, yet August gave the largest month's coal output for the year. This would have been greatly exceeded in the following month, had the cancelling of contracts due to strike conditions not brought about dull trade. General Superintendent A. S. McNeil of the Cape Breton district fully expected to bring the output up to 400,000 tons per month, and this would have been done and exceeded had trade conditions remained favorable.

During the war period, and succeeding it, Mr. McDougall and his associates and assistants had a very difficult situation to cope with. The forming of the British Empire Steel Corporation has aided in settling some of the difficulties. Due to the policy laid down when the Corporation was organized, the condition of the collieries has been gradually improved. Equipment and development have kept pace with requirements. Plans for opening up new collieries have been made, and work commenced on some of these. Present conditions favor large outputs. Good ventilation systems have been put in at large cost, large fans installed, air courses opened up and carried into the coal faces. Permanent stone stoppings and overcasts have been built for the safety, health and comfort of the miner. The haulage systems have also been improved and extended, and the best methods known to modern mining engineering have been employed in mining coal.

The relation between the workmen and officials at the Sydney Steel Works is better now than for many years. All, or nearly all, are now working in harmony and trying to usher in a new day. This has had its effect on the outputs and new records have been made, and if trade conditions remain favorable it will sooner or later be realized fully that the co-operative spirit is the only one that will succeed in this old work-a-day world.

Mr. McDougall, as he retires, leaves the plants and mines in good condition, and the workmen better satisfied than for years past. We would have wished that Mr. McDougall could have remained to share the better conditions brought about by his own efforts; but having decided to retire from the active management of the Corporation, the *Canadian Mining Journal* wishes him success in all his future life and undertakings.—J. M.

"DICTATING PRICES"

The daily press of the United States and Canada, the dealers and the politicians are having much to say relative to the price at which gasoline should be sold and are setting themselves up as judges of a business about which they know very little. In this connection we believe the following editorial, which appeared in the August 30th issue of the *Oil & Gas Journal*, published in the United States, will be of interest:—

What would the farmers think, asks a student of the oil industry, if the grocers of the country were to unite in a demand for 80-cent wheat on the ground that there was an over-production?

It is easy to imagine the indignation of the farm bloc in Congress, the scathing satire with which they would refer to the "tail wagging the dog," the striking comparisons they would draw between the investment of the farmers, their risks and labors, and the comparatively small amount representing the grocer's stock of flour and bread.

Yet, this observer continued, is not that a practical analogy of the situation in the oil business? The producers with billions of dollars at stake, the refining branch with hundreds of millions invested, find their business jeopardized by the clamor of dealers whose own supply is dependent upon the successful operation of the producing and refining industries.

What other business shows the dealers attempting to dictate the price of product to those responsible for the production and manufacture? Do we hear of the automobile agencies throughout the country conducting a public agitation to compel the manufacturers to reduce the price of cars below cost? If they did and, by any possibility, through the aid of political pressure and public agitation, they could succeed in forcing their wishes on the manufacturers, how long would they have any cars to sell? No law and no agitation can compel men to do business at a loss, even if it were economically conceivable that they could attempt it.

Why, then, it is asked, should that sort of thing be forced upon the oil industry? The farmer can regulate his production by his acreage; the automobile manufacturer will not allow production to outrun the "saturation" point if it arrives. The oil producer has no such check on the discovery of new fields or sands and the refiner is likewise at the mercy of forces he cannot foresee, surely all the more reason why dictation of oil prices is more unreasonable and, indeed, impossible than in either the wheat or motor markets.

These facts are evident to all oil men in the producing and refining branches and should be equally plain to distributors and the consumers if they would stop to inform themselves and think it out. But the oil business has been for so long regarded not as a business but as a game of chance, as a target for criticism and abuse without the slightest basis of knowledge, that it seems almost impossible to attempt to secure a fair hearing for it in the court of public opinion, swayed by demagogic assertions by self-seeking politicians who are quick to take advantage of dissensions within the industry to further their own purposes.

This agitation against the oil business comes with all the less grace from the Senatorial, Congressional and Gubernatorial champions of the farmer suffering from an over-production of wheat. If they were only fair about it and would put themselves in the oil men's place they would be as indignant at the attempt to dictate the price of oil to the men who produce it as they would be if the grocers were to begin an agitation for fixing the price of wheat below cost.

SMELTING ZINC IN THE ELECTRIC FURNACE

The publication of Bulletin 208, "The electrothermic metallurgy of zinc," by B. M. O'Harra, associate metallurgist, is announced by the United States Bureau of Mines.

Zinc smelting is frequently termed a backward art, states the author of the bulletin. The term is hardly true, for great progress has been made in recent years in the design and in the thermal efficiency of the retort furnace, in the quality of retorts, in the recovery of zinc, and in the ability to treat more impure and complex ores. The fact remains, however, that the peculiar physical and chemical properties of zinc have delayed such immense advances — large smelting units, high recovery, low-unit costs, and ability to treat low-grade ores — as have been made in the metallurgy of lead and copper.

Much work has been done in an effort to find cheaper and more efficient methods of recovering zinc from its ores. Various methods have been proposed for smelting in the blast furnace. Some of these contemplated the production of zinc vapor and its condensation to liquid; others attempted to produce liquid zinc directly by smelting under pressure. It is now realized that fundamental difficulties render these proposals impracticable.

The electric furnace for smelting offers obvious advantages in the way of the efficient utilization of energy, large units, easy attainment of high temperatures, and the possibility of treating complex ores.

E. H. and A. H. Cowles first suggested a design for an electric furnace for the reduction of zinc ores in 1885. In 1900 several investigators started work upon various processes and had more or less success. The chief difficulty they encountered was the impossibility of obtaining more than a small amount of the zinc as liquid metal because most of the zinc vapor condensed as blue powder. Interest in the electrothermic metallurgy of zinc increased, until in 1914 and 1915 the problem seemed to be approaching solution. About this time the hydrometallurgy of zinc sprang into the limelight and a commercial process was soon perfected. This rapid development, perhaps aided by the war premium on the high-grade spelter produced by electrolytic deposition, distracted attention from electric smelting to some extent, though progress continued.

With the perfection and standardization of the electrolytic process has come a better realization of its limitations, especially the necessity for large-scale operation and the difficulty of obtaining high extraction. Because of these limitations the electrothermic metallurgy of zinc still has a field of its own and in fact promises to become a strong competitor of both hydro-metallurgy and retort smelting except under conditions highly favorable to the latter methods.

Because of the imperfections of the retort and electrolytic processes and the promise that the electric furnace offers in overcoming these imperfections, the United States Bureau of Mines, in co-operation with the Missouri School of Mines and Metallurgy, has undertaken a study of the electrothermic metallurgy of zinc.

IMPROVED VOLATILIZATION PROCESS FOR ZINC-LEAD SEPARATION

In connection with experimental work on modifications of chloride volatilization process, on which the United States Department of the Interior has for some time been engaged at the Intermountain experiment station of the Bureau of Mines, Salt Lake City, it is now announced that in several cases chlorides are left out of the ore entirely and oxides are volatilized. For mixed zinc-lead ores it is possible to so alter them by roasting that the volatile lead oxide can be removed from the ore by further raising the temperature, using a rotary kiln for this latter step of the work. Lead can be almost completely cleaned and even some of the silver removed from roasted zinc concentrate containing the usual small amounts of lead. This has already been shown by tests on a semi-commercial scale at Harbor City, Calif. It is believed that not only can this method be used with possible profit by the zinc smelters, but that it is entitled to favorable consideration as a means of concentrating ore. This work is about ready for larger commercial tests and the Bureau of Mines is now desirous of getting in touch with organizations who would be benefited by the use of this modified process and who possibly already possess all the necessary equipment required for the tests.

PROPERTIES AND USES OF TANTALUM

Pure tantalum, which can be produced from tantalite and manufactured into sheet, rod or wire, is quite soft, having a melting point next to that of tungsten, and is characterized by great ductility. Chemically, tantalum is exceedingly inert to the action of all chemical reagents. The only acid which will attack it to any extent is hydrofluoric acid. Present or possible uses include parts of wireless valves, dental instruments, filaments for incandescent lamps, analytical weights, etc. One of its most interesting properties arises from the fact that it can act as an electrolytic valve so that with a suitable set-up alternating current may be converted into a direct pulsating current, which can be used for charging storage batteries. Its property in this respect is similar to that of aluminium, but in the case of tantalum there is no problem due to the corrosion of the metal. The use of this metal for chemical equipment in the larger sizes will ultimately depend upon the cost at which it can be produced.

THE DUST PROBLEM

By H. S. SALTON

One of the great problems confronting mine, mill and factory management is that of dust. Any dust is a menace to health. An irritating, dust-laden atmosphere is the cause of more trouble than most persons realize. The health and efficiency, and hence the productive powers of the men are impaired, the wear and tear on surrounding machinery and property is increased, the protection against fire loss and explosion is lowered, the loss of men's time due to sickness and disease, caused by inhaling the impure air, is great and in many cases the saving of dust is a source of revenue because of the values carried in the fine material. Therefore, the firm owning and operating a plant in which dust is prevalent should protect itself against this menace by an investigation of conditions and the installation of suitable appliances for the elimination and collection of this dust.

Dust breeds disease; it carries germs; it affects the brain, lungs and eyes, and causes head-aches. Fresh, pure air is essential to good health. The management of one prominent plant claims that, since putting in a dust collecting system, the absence of employees from work has been reduced 85 per cent.

Some Sources of Dust

What are the sources of dust? They are so numerous that it would be difficult to enumerate them all, but we shall consider a few of the causes in mills treating the products of mines.

Dust emanates from the crushing and grinding machinery, and, in fact, wherever a dry process is used the surrounding air is sure to be laden with dust. When rock breakers are fed with ore direct from skips from the main hoisting shaft, the rush of ore over the grizzly results in a load of dust which, if the breaker is enclosed, remains in the air most of the time. Often there is a circulation of this air and the dust is carried away. This loss of value is of small consequence in the case of low-grade ore in contrast to the improved health and comfort of the attendants resulting from a dust-free atmosphere.

The undersize, when passing through the grizzly into the bins, also causes considerable dust. When skips or mine cars are dumped into bins and thence fed to the breakers, dust conditions are improved somewhat. The broken ore, flowing out onto the belt conveyors, throws off a good deal of dust, but this can be prevented a little by covering with a hood and an exhaust system. A spray is very effective, especially if a wet treatment is to be used where addition of water will have no ill effects.

All dry crushing mills are very dusty even when enclosed tightly; but they may be rendered almost dustless by exerting simple precautions. The casing can be connected by a metal pipe to a fan, but stop the fan for a moment and the dust arises in clouds. A fan is really necessary for the best working of such a machine, the protection of bearings and other machinery and the comfort of the attendants.

If belt-and-bucket elevators are used, both elevators and bins can be made almost dust-proof without much trouble. If built of wood, they should be double lined; if of sheet iron, they should be bolted or riveted with felt joints. If left undisturbed, all corners and small openings in conveyors, elevators and bins naturally become sealed by the dust collected within them, thus preventing the exit of dust to the plant. Chain-and-bucket elevators, if well constructed of plate and angle iron, make little dust and may be kept clean by means of a suction fan placed where they discharge. Pits in which the boot of an elevator is fixed should always be roomy and as shallow as possible.

Poisonous Dust

Dust is especially injurious where lead or zinc ores are being treated. The disease known as lead poisoning is appallingly frequent and the crippled condition of workmen whose systems have become affected with zinc dust and fumes is indeed pitiful. In the writer's experience, at one mill, treating zinc ores, the mill was in such a dusty condition that it was almost impossible to see more than a foot in front of one, and the working life of the mill men was very short, as paralysis of the limbs set in and the men were physically unfit for any real labor.

In many cases there is the danger of loss from dust explosions. Although not common in the metal mining industry, the subject is worthy of consideration, as the treatment of coal comes under this heading. To avoid dust explosions the proper and natural thing to do is to eliminate the dust. Thorough ventilation is of prime importance and naked flames should be avoided in plants where the production of dust cannot be prevented. Machines that may become overheated should be watched and the air around belts that may generate static electricity should be moistened by spraying or, as is most often practised its collection prevented by a wire to ground.

Processes that cannot be safeguarded effectively by the methods previously mentioned should if possible be conducted in a separate building, adequately protected from contact with surrounding property and with the machinery so arranged that it can be stopped and started from the outside.

Dust-Collecting System

Great care should be evidenced in the selection of a dust collecting system. As far as possible, have metal air trunks, steel plate exhausters, and metal dust collectors; and where settling chambers or dust rooms are used, these should be built of metal. In many instances the dust is in such a finely divided state that cloth strainers have to be used. Under this condition, if the dust is inflammable, it would be advisable to place the apparatus in a separate building with a system of sprinklers and a fire alarm, so that in case of fire, the chances will be in favor of a greatly reduced damage to property and perhaps to life.

In passing, one should mention the undoubted value of saving dust. In the mineral industry, dust is almost always worth saving, as its value is equal to, if not greater than, the ore being milled. Fines usually carry good values, and great care should be taken to keep the loss of fines down to a minimum; it is well worth a little trouble and expense. Their treatment is a little difficult, but a mixture of dust and raw ore has often been used to feed the furnace without any ill effect.

Details have not been discussed fully above; but the writer wishes to draw to the attention of those engaged in the management of industrial plants, the menace from a disregard of the dust problem. The destructive power of dust, as well as its possibilities as a source of revenue, should be considered. Study your dust problem and seek the advice of an expert. An efficient dust collecting and ventilation system is an essential apparatus in any dusty mill, from the standpoint both of sanitation and of economical operation.

INDUSTRIAL USES OF NICKEL

Sir Alfred Mond Outlines Post-War Development of Nickel Industry

Recently, in speaking to the shareholders of the Mond Nickel Co. at their annual meeting, the Chairman, Sir Alfred Mond, gave some interesting information about the Company's business. In spite of the trade depression, he announced, their financial condition had improved.

The demand for nickel, which had been at a very low ebb, had sustained a very considerable improvement during last year, an improvement which at present was maintained, and their turnover and deliveries had been satisfactory. Their products had been increased, and their works were well employed, but the prices which had been ruling, owing to a somewhat unrestrained competition from a good many sources, had been lower than almost any other period of the industry, and had counteracted to some extent the benefits derived from the larger sale and the larger production. Copper sulphate, of which they were the largest manufacturers in the United Kingdom, and which was the product which was chiefly exported to the Continent had suffered not merely from competition but also from severe fluctuations in the exchanges in most of the bigger export markets, such as France and Italy.

So far as the operating plants were concerned their Canadian colleague, Mr. Corless, recently visited England, and told them that as regards both the present and future of the mines and other plants there was nothing but satisfactory things to report.

New Uses for Nickel

The use of nickel for cooking utensils was on the increase. The firm of Messrs, Sankey & Co. had taken up the manufacture of nickel cooking utensils from nickel sheets rolled by their subsidiary company, Henry Wiggin & Co. Ltd., of Birmingham. The consumer had yet to be educated and to realize that whereas solid nickel-ware was more expensive in original outlay, it lasted for ever, required no repairs, and had great hygienic advantages.

Then, of course, the motor-car industry was beginning to awake to the fact that nickel looks better than brass, remains cleaner, and does not get tarnished, and we saw now cars with raditors, radiator coverings, and other fittings made of nickel-copper alloys. That was to spread. Then, again, the resistance wires, which were used for electric heaters and fires, which were becoming more popular, were made of nickel alloy and here again there was room for further development. These were a few out of a great many uses of nickel and nickel alloys, including the new alloy which Messrs. Henry Wiggin & Co. were putting on the market — "Corronil." There was no doubt a great demand for non-corrosive metal, which can be rolled, and is easily workable in a machine shop. The alloy, with a large proportion of nickel in it, had very high corrosion-resisting qualities. Their nickel mines were some of the largest and most important in the world, and all operations had been carried on smoothly and efficiently. As regards the refining works in South Wales, there again, results were very satisfactory. Relations with the workmen were harmonious, and they had every reason to be satisfied that those who had the more immediate charge of their very interesting, difficult, but cheap process of manufacturing nickel at those works were doing good work.

Nickel Coinage

The Chairman proceeded to draw attention to the changes which had taken place in the uses of nickel since the war. Previous to the war, he said, probably 50 per cent. of their nickel had gone to steel makers for armaments and 50 per cent. for the production of non-ferrous alloys and pure nickel products, whereas last year only 12½ per cent. had gone to the former and 87½ to the latter. That was counteracting the effect of the Washington Treaty on the manufacture of armaments. The use of nickel for coinage was increasing, many countries now replacing their paper currency with nickel. The Italian Government, for instance, had recently placed large orders for the supply of pure nickel coinage, this company obtaining the contract for the supply of the raw material. A similar contract had been obtained for one of the Baltic States. They had also supplied considerable quantities of nickel for other pure nickel and nickel-bronze currencies in various parts of the world.

He desired to say a word or two about their subsidiaries, Henry Wiggin & Co. Ltd., of Birmingham, and the American Nickel Corporation. Their company acquired all the shares of Henry Wiggin & Co., a very old-established and much-respected Birmingham firm, some time ago. In last year's report the directors stated that no dividends had yet been received on that investment. The firm, like most others, were hit by the sudden depression in trade. The board were well aware of the fundamental soundness of that business, and were not unduly alarmed at the temporary setback. In that view they were quite justified, because this business was now very well occupied, and was extending its operations, justifying entirely the anticipations which were formed. Nickel alloys were the special business of Henry Wiggin & Co., and they were also operating the rolling mills for making nickel sheets and pure nickel material of that kind. Their works were now well employed, and are turning out a very good product.

The Clearfield Plant

With a similar view of policy, the board took a considerable interest in a business in Clearfield, Pennsylvania, which had been laid out to manufacture a variety of nickel goods — rods, sheets, wires, and also their new alloy, "Corronil." They had recently had an opportunity of conferring with them, and two of their board — Mr. Owen Evans and Mr. Philip Mond — had been twice this year to America in order to study the situation on the spot. Here again they had a business which was not making any return at the present moment on the capital outlay, but which had great future value for the shareholders of the company. First of all, it gave an outlet for their nickel in the largest market for nickel in the world to-day, the American Continent.

Uses for nickel in that country would be very great. One of the most interesting developemnts in connection

with that side was the use of malleable bar nickel for turbine blades, with which that well-known firm, the Westinghouse Company, on that side of the water, were to-day carrying out very important experiments.

ECONOMICAL USE OF MINE TIMBER

That the consumption of timber in the mines of the United States has practically doubled within the past twenty years while the cost has in some districts increased three to five times is developed as the result of a survey of the mine timber situation just completed by the Department of the Interior, through the Bureau of Mines, in co-operation with the Forest Service. In many regions formerly well forested, it was found that the timber supply has dwindled until the cost of freight to the mines equals the cost of the timber at point of shipment. The object of this survey was to determine the cost and consumption of mine timber, and to study methods of selection, treatment, storage and use of mine timber, with especial regard to economies that might be effected, particularly by preservative treatment.

The Bureau of Mines has in course of publication a comprehensive bulletin, which points out to the mine operator ways in which he can reduce his timbering expenses and at the same time conserve the diminishing supply. The chief means available to mine operators for lessening timber expenses are greater care in purchasing by selective grading as practised in the lumber industry, rather than by the old method of purchasing by species; paying more attention to the benefits derived from peeling and seasoning, and proper storage, to prevent decay before use; and treating with a preservative those timbers which are placed in the principal openings, in order to prolong the life of the timber, and permit in many instances the use of less durable species in place of the more durable varieties.

PEAT BOG SURVEYS

Four peat bogs in Quebec were surveyed by A. Anrep of the Geological Survey during the field season of 1922. The results are reported in *Summary Report*, 1922, *Part D*, which includes maps of the first three.

The Sagamite bog, 13 miles north of Quebec city, is shown to contain recoverable peat equivalent to 481,000 tons of peat fuel. The ash content is rather high, but otherwise the peat is suitable for the manufacture of machine peat.

The Breakeyville peat bog is crossed by the Quebec Central Railway 13 miles south of Levis. The half west of the track is not deep enough for the economical use of a peat machine, but would provide excellent hand-cut peat. The part east of the track contains 847,000 tons of potential fuel, and is especially well suited for the manufacture of machine peat. The ash content is very low—about 5 per cent.

At St. Jean, 2 1-2 miles north of Breakeyville and 9 miles from Levis, is a small bog containing 225,000 tons of good potential fuel with a low ash content. It is suitable for a small mechanical plant.

At Ste. Thérèse, 20 miles northwest of Montreal, is a bog of 1,070 acres in extent, but too shallow for the use of a peat machine, that contained 460,000 tons of potential fuel. The fires of 1922 reduced his amount considerably. During the summer of 1920 an unsuccessful attempt was made to utilize this peat by cutting it by hand and then drying it in a draft of hot air.

The first three bogs described offer convenient sources of good fuel and will, doubtless, be put to use when the commercial manufacture of peat fuel becomes established.

THE PEAT INDUSTRY OF THE UNITED STATES

The annual report on the peat industry of the United States shows that it made substantial progress during 1922. The number of operating companies increased from 21 to 23, and the production increased almost 100 per cent. over that of the previous year, while the total value increased 52 per cent. Of the 60,680 tons reported, 1,040 tons was used as fuel, 1,893 tons as stock food, and the remainder as fertilizer. Thus the peat industry, though still of small dimensions, is growing satisfactorily.

DOES COMMERCIAL SECRECY PAY?

The contrast is so often made, and almost invariably to our disparagement, between the policy of secrecy generally pursued by British firms and the policy of openness said to be followed by firms of other nations, notably American and German, that it is difficult to dismiss it as merely imaginary, says "The Chemical Age." The latest reminder on the subject comes from Mr. J. A. Reavell, an engineer familiar not only with British but with French and American practice, who returns from the United States impressed with the frankness with which people over there discuss their business. Not only is their plant freely open to inspection, but the visitor is shown their costing sheets, the details of their organisation, their methods of soliciting business, their advertising schemes, and all the rest.

Rarely does a British visitor undergo such an experience without surprise. Why, he naturally asks, should the American business man be so open about his business while rivals at home are so close? How can he afford to give away so freely secrets so jealously guarded at home? The explanation is to be found in a totally different attitude of mind. What we insist on regarding as vital secrets of trade are no secrets at all in the States—it is doubtful, indeed, whether even here they are secrets except in name. For, whether one takes the manufacturer or the merchant, there is very little in either case with which competitors are not already familiar. But we keep up the pretence of knowing things that nobody else knows, while the American business man has frankly given it up.

The gain, we think, is on his side. When a dozen engineering or chemical firms decide to exchange plans, each member who gives something to the remaining eleven gets in return much more. Relatively to one another they remain on the same level; the only difference is that all are better informed, and the more capable, therefore, between them of upholding the industry in which all are engaged as against outside competitors. Here, the opposite policy is pursued. Between manufacturers, between merchants, between consultants, even between societies, there remains an astonishing spirit of suspicion. Each prefers to act in isolation, believing that by so doing he can best keep ahead of his neighbours. Which is really the better way? We are strongly inclined to think that the collective attitude in the end pays better than that of isolation. The doctrine of living too much to oneself often proves bad business as well as bad ethics.

NEW METHOD OF LEACHING COPPER ORES

Technical Paper 312. "Leaching nonsulphide copper ores with sulphur dioxide," by Charles E. Van Barneveld and Edmund S. Leaver, has just been published by the United States Bureau of Mines.

This process was devised to provide a cheap and efficient method for treating the so-called "porphyry" copper ores of the Southwest, generally containing both "sulphide" and "nonsulphide" copper minerals, mixed in such proportions that they can only be satisfactorily treated by a method that will concurrently recover both the sulphide copper and the nonsulphide copper. The importance of the matter may be judged by the fact that more than one-half the copper produced in a recent year in Arizona and New Mexico, amounting in value to $106,000,000, came from the so-called "porphyry" low-grade deposits.

It is thought by the Bureau of Mines investigators that the sulphur dioxide leaching process, developed by the Southwest experiment station of the bureau, in co-operation with the Miami Copper Company and the Arizona Copper Company, is suitable and commercially available for a wide range of the ores above described.

Summed up, the advantages of leaching with sulphur dioxide are as follows: The plant is compact and not expensive; there are no installation difficulties; power requirements are light. Operation is simple and easily controlled; there are no delicate adjustments or critical points. Percolation difficulties common to leaching are entirely avoided. Perfect contact is assured between the finest ore particles and the reagent; thus there is excellent utilization of the reagent, which is very cheap. In consequence the process may be extended to ores with so much acid-soluble gangue that they could be treated at a profit by ordinary sulphuric-acid leaching. The process is as applicable on a relatively small as on a large scale, and small-scale operation does not necessitate an undue increase in operating cost.

JADE, AMBER AND RUBIES IN BURMA

Burma is famous for its jade. The greater part of the jade of fine quality is exported to China, whose fondness for the apple-green tinted jade is well known. The production of jade from April 1, 1921, to April 1, 1922, amounted to 3,815,035 hundredweight, valued at 701,673 rupees ($226,346), averaging 5 cents a hundredweight (112 pounds).

Burma has only a small output of amber and that produced is not considered by experts to be as desirable as Baltic amber, being harder. It is found in clays of probably the Miocene age. There is little variety in the color, which is bright cherry yellow with a reddish tint that fades into a dirty brown. It is used in the manufacture of rosaries and Burmese ornaments. Little is exported save in the form of beads, which are pretty and effective but not generally popular even in Burma.

According to a British publication, next to petroleum rubies are the most valuable mineral product of Burma. Concerning their origin the author states:

"They are found in a variety of places — at Manyaseik, in the Myitkyina district; in the stone tract of the Sagyin Hills, in the Mandalay district; and in small quantities in a few other places. The only place, however, where the returns are really profitable is the Mogok area, about 90 miles northeast of Mandalay. The Ruby Tract proper, consisting of mines at work and those abandoned, extends to about 66 square miles. The area in which mines are in active operation covers 45 square miles."

The Burma Ruby Mines Co. has the sole lease to extract precious stones from certain areas in the Katha district, where they are at present found. The production in 1921 was 112,197 carats, valued at 691,209 rupees ($222,971).

A small quantity of sapphires and spinels are also mined. — Commerce Reports.

A RESPONSIBILITY OF THE BRITISH PEOPLES

General Smuts has been particularly eloquent in appeal to the reason and better feeling of the world. In more than one speech recently he has emphasized his view that the British Government is seeking to save the world from irreparable disaster. What is wanted in the world to-day is some of the spirit shown in South Africa since the Boer War. At the unveiling of a memorial to General Botha at Durban, General Smuts said: — "This monument is not only a monument to reconciliation; it is the Englishman's hand stretched out to the Dutchman in South Africa, and it shows that the conflict is passed for ever from our country. General Botha was one of those men whose work will be measured by the centuries...To-day, it is a great leader like General Botha; to-morrow it may be a great leader of English origin; but whatever it may be, let us hope we shall always have such sane and wise and faithful leadership." And the moral might well be pointed from another utterance in another part of the Empire. In a speech in New Zealand, Sir Harry Lauder is reported to have said that "unless the nations of the world get together, you will be bringing up your son to die just as my boy died. But I can at least see through the mist. The salvation of humanity lies in the unity of the great British Empire. The rest of the world does not know that we want them to be friendly with us. I am out for friendship. We can get it by substituting vision for vanity, partnership for petulance, and trustfulness for suspicion." — United Empire.

RESEARCH ON THE RAND

In a recent address to the Chemical, Metallurgical and Mining Society of South Africa, its president, Mr. F. W. Watson, dealt with the beneficial results of practical research work on the Rand. This work is carried on mainly in the laboratories, mines and mills of the large companies, and by them is regarded as a necessary and remunerative investment. Among the problems investigated have been the economical use of fuel in the boilerhouse; the sampling of supplies of all kinds, from soft soap to calcium carbide; the dust problem; the use of mine water in steam plants and in the mills; the use of mine timber and its preservative treatment; the quality and preparation of drill steel; and numerous phases of gold metallurgy. In a number of cases the results obtained from these researches have been of benefit to the whole world of mining men. Concerted action alone has enabled these Rand investigators to solve some of their problems, and the results have been made freely available to miners and metallurgists elsewhere.

The Yukon output of gold for the first six months of 1923 is 341,991 ounces, which is 12,887 ounces less than for the corresponding period last year.

THE MINING DISTRICTS

By THE JOURNAL'S CORRESPONDENTS

QUEBEC

An official statement to the shareholders of the Noranda Mines Limited gives details of the recent discovery made on the southerly claim of the company's property in the Rouyn district of Northwestern Quebec. The new find, which covers an area of approximately 800 feet in length by 300 feet in width, is considered to be the most important discovery on the company's property. This area consists of crushed and brecciated lava flows, which have been cemented and replaced by quartz, pyrites and carbonates. Visible gold is found over a considerable portion of the area, but surface trenching and samplings done to date indicate that ore of commercial grade will be confined to the fractured zones, where the alteration of the lavas has been greatest. A trench across a portion of the ore body has shown two sections, one giving an assay of $9.00 across 8 feet, and the other $15.00 across 15½ feet. An additional 5 feet of ore adjoins the latter section, from which assay returns had not been received. These two sections of ore are separated by 63 feet of material, carrying an average value of $2.25 a ton, and this gives a total average value of $5.00 across a total width of 90 feet. Fifty feet to the north a parallel trench has shown two sections, one carrying $4.80 across 11 feet and the second section $11.00 across 25 feet. It is understood that since the report was issued further work has been done, adding to the importance of the discovery. It has been decided to start diamond-drilling on the ore-body at once, and also to sink a three-compartment shaft

Stabell To Be Developed.—Those who have taken over the Stabell property in the Harricana district of Quebec have contracted for a shaft to a depth of 300 feet and also for 400 feet of drifting and crosscutting at the 300-foot level. A small plant has been installed. The schedule provides for the shaft reaching the vertical objective by New Years. Then the richer section of the shear zone as determined by diamond drilling will be tested.

New Staking and Assessment Regulations Mooted. The Quebec authorities are moving in the matter of the new gold-mining development. Transportation and postal facilities to the Rouyn district are to be improved and more work will be required if ground staked by prospectors is to be held.

Heretofore the holder of a prospector's license has been able to stake one 200-acre claim, on which he must do twenty-five days work the first year and twenty-five days during the second year, and thereafter the same on each fraction of forty acres. The new provision will permit the staking of five 40-acre claims on each license, but twenty-five days' work will have to be done on each during the first instead of the second year.

By this commendable arrangement it will be more difficult to retain ground without doing work. If prospectors are given better means of access to the Quebec gold fields, they must show their willingness to find something, instead of holding on until others find something.

It is understood the Prime Minister of Quebec has given these matters his personal attention, for developments are attracting attention and his desire is to promote constructive activity.

NORTHERN ONTARIO

Gowganda. — The Castle-Trethewey has decided to proceed with the erection of a mill. In order to finance the construction and to carry on operations until the property is producing, there will be issued $200,000 of preferred shares. These shares will bear interest at the rate of 7 per cent., and will be offered to shareholders at 80. They are to be redeemable at any time, at the option of the company, and probably will be paid off from the first available earnings. Ore reserves stand at 1,363,000 ounces, which is an increase of 640,000 ounces during the past year. Since this estimate was made, a vein has been found that shows a considerable amount of high-grade ore, which has not been included. During the year, production amounted to 53,000 ounces, which was obtained by hand sorting.

South Lorrain. — The Keeley financial statement as of August 31st shows quick current assets of $711,000, which consist of cash, government bonds and ore on hand and at the smelters. The Ontario government has purchased a piece of the No. 26 vein, which in one place showed a width of almost 5 feet of 7,000-ounce ore. The piece purchased by the Government weighs about two tons and is the most valuable single specimen of ore which the government possesses.

It is announced that the Lorrain Consolidated has provided for future financing from the sale of part of the treasury stock. The company has 1,000,000 shares still in the treasury.

Cobalt. — The Kerr Lake Mining Company has declared a dividend of 12½ cents a share, payable October 15th to shareholders of record October 1st. The Kerr Lake is financing the Goldale property in Porcupine, the shaft of which is now down 1,000 feet.

The Nipissing has declared a dividend of 3 per cent. payable October 20th to shareholders of record October 1st, and in addition has declared a bonus of 3 per cent. This will call for a disbursement of $360,000

During the month of August there was shipped from the Cobalt camp a total of 898 tons of ore, concentrates and residues. Of this amount 736 tons went to the Deloro Smelting & Refining Company in Ontario, and 162 tons to the American Smelting & Refining Company at Perth Amboy.

Kirkland. — Mr. T. E. Godson, Mining Commissioner, has adjourned proceedings in the tailing dispute brought against the Kirkland Gold by the Teck-Hughes company, as it is hoped that an amicable settlement may be reached. The Teck-Hughes was asking for an order to restrain the Kirkland Gold from depositing tailings on Teck-Hughes ground, and was also asking for damages in respect of the ground that had been covered. The question of tailings disposal is likely to be of increasing importance in Porcupine and Kirkland, and it is to be hoped that the Teck-

Hughes and Kirkland Gold may reach a private understanding. It would be an exceedingly unfortunate thing if damages were to be assessed, as some people have hoped they would be, on an acreage basis, as this would establish a precedent for future litigation. The Teck-Hughes is understood to be producing at a record rate, and it is stated that the output for the first half of September was over $60,000. The annual report for the year ending August 31st will be published shortly, and will show substantial increases in both production and profits. Ore reserves, which were shown last year at $1,183,000, will be practically doubled this year. Development work on the 1,100-foot level is understood to be giving better results than when the veins were first intercepted at that depth.

The Wright-Hargreaves has declared the regular quarterly dividend of 2½ per cent, payable October 1st to shareholders of record September 15th. This dividend calls for $68,750 and makes a total of $687,500 paid to shareholders to date. Production is being maintained at the rate of approximately $60,000 a month, but enlargements are being made gradually in the mill, and some time next year this output would be substantially increased.

Officials of the Montreal-Ontario state that good values have been encountered on the 450-foot level. At this point there are two veins, about 30 feet apart, and one of these shows a width of over 12 feet.

On the 800-foot level of the Tough-Oakes Mine, an ore-body is being developed that constitutes the most important discovery made on the property in the past several years. Over 100 feet of drifting has been done, with values ranging from $15.00 to $90.00 a ton, and the vein has a width of from 5 to 6 feet. This ore is being followed toward the Sylvanite line, which gives additional speculative value to the latter property.

Larder. — The Crown Reserve Company has purchased a 150 h.p. Diesel engine for its Larder Lake property. This will permit of more extensive development being carried on at the 550-foot level, and will also allow of work being carried on to a greater depth.

Painkiller Lake. — At a meeting of the Hattie and Beatty Gold Mines, held a short time ago, it was decided to increase the capital of the Hattie to $5,000,000 and to take over the Beatty claim. Shareholders of the Beatty will be given one share of the Hattie stock for each one they now hold. Of the $5,000,000 Hattie capital, 1,838,000 shares are outstanding, and 1,450,000 shares will go to Beatty shareholders, leaving 1,712,000 shares in the treasury. An option on 500,000 treasury shares has been given to Mr. W. W. Butler of Montreal, at 25 cents a share.

Porcupine. — The Nighthawk Peninsular Mines will sink a new three-compartment shaft, which will be about 250 feet east of the mill and 800 feet east of the present shaft. The location of the shaft was decided upon after diamond-drill holes had been put down. Every effort is being made to get the mill in shape so that operations will be started some time in November.

The Dome has declared the regular quarterly dividend of $1.00 a share, payable October 20th. It is understood that after this date the capital of the company will consist of 1,000,000 shares of no par value instead of the present capital of 500,000 shares of $9.00 par. There have been no recent developments of particular importance at the Dome, but underground work continues to yield satisfactory results. Production is at the rate of approximately $400,000 a month.

Tonopah Company Drops Options.—There is general regret that the Tonopah Company, with its experienced field forces has decided to abandon the two Kirkland Lake and one Shining Tree properties it undertook to exploit. The incident is not without a moral. King Kirkland capitalization was increased to $5,000,000 by the Jordan-Wettlaufer interests. Tonopah, after a try-out declined to go further. Its action in the matter should have an educational influence. Half the Shining Tree story has not been told. Duplicity on the part of some concerned did not aid the success of the undertaking, nor does it inspire a greater degree of faith in a certain type of promoter.

NOVA SCOTIA

"Bump" at Springhill.—Two men were killed in No. 2 Mine, Springhill, both being buried in coal thrown out from the face and sides by a "bump". It was a local disturbance, but about sixty feet of the track was thrown up, and a number of the timbers displaced. Springhill has been grappling with the problem of sudden strata movements for a number of years. The method of mining was modified to meet the dangerous and uncertain conditions. For a time it seemed that success had been obtained, but of late bumps have become more frequent and there is considerable anxiety among the workmen. The management of these collieries is very efficient, and has studied from many angles the question of sudden exertion of strata pressure. Having changed the method of mining to overcome the difficulty and having failed partially in its purpose, the management is ready to go still further if it is found necessary, and to introduce a new system. But it must be thoroughly demonstrated that the present method has failed and further modifications may be necessary before this is done. The quality of the coal from this mine is excellent and in great demand, and in order to keep the output up to demand the best mining engineers of Besco are working on the vexed problem of bumps.

Nova Sotia Miners to Decide their Own Status.—A Glace Bay lawyer representing the United Mine Workers in Nova Scotia together with National Officer Frampton went to Indianapolis to state the case of the miners and their views on remaining in the organization. President Lewis made it quite clear that the matter was largely in the hands of the miners themselves. He stated that they could either stay in or go out as they pleased. He would do nothing to coerce them, either way. If the laws of Canada were so constituted as to give no protection to the U. M. W. A. as a labor organization, then he would not fight against the law. The miners are free to choose their own course, but if they decide to stay in the union then they must understand that the laws of the organization must govern their action. A convention will shortly be held to determine what action will be taken in the matter. Outside of the U. M. W. there are the Russian Reds, the O. B.U., the I. W.W. and the Workers' Party of Canada, all of the same color so that there is little to choose among them.

Officials Inspect Plants.—Mr. Roy Wolvin, President of Besco, Sir Newton Moore and Messrs. D. F. Downe and Franklin have made a tour of inspection of the Steel Works and Collieries. Messrs. Downes and Franklin are both Americans, the former having been

President of the Lackawanna Steel Company for years. This company operated several coal mines for the purpose of supplying their steel plant. When the inspection is complete and a report made, changes in the executive will take place.

"Mecco" Rescue Apparatus Selected.—J. J. McDougall, Assistant General Manager of Acadia Coal Company, attended a meeting in Cape Breton at which the merits and demerits of several types of rescue breathing appartus were discussed. The "Mecco" was selected as being the most suitable for the Nova Scotia Collieries although it was openly admitted that each type of apparatus had its own advantages, which under different conditions might make it commendable. The "Mecco" is of British design, and like all other types is being constantly improved. All the colliery districts of Nova Scotia will be equipped with the same type of apparatus. This will enable the corps of one district to render effective aid in any other district should an accident occur necessitating outside help.

BRITISH COLUMBIA

Crown Granted Claims Now Open.—A list of British Columbia Crown granted mineral claims that have reverted to the Crown since 1919 for non-payment of taxes and now are subject to lease under Section 180 of the "Taxation Act", has been issued. There are more than 2,000 such properties and they are to be found in every mining district from Vancouver Island to the extremities of East Kootenay. When it is remembered that to secure a Crown Grant there must be an expenditure of at least $500 under the provisions of the "Mineral Act", some idea may be had of the large sum that has been spent on holdings that now have found their way back to the Crown. This, however, should not be construed as a reflection on the mineral possibilities of the Province, for there is no doubt that a large proportion have been relinquished by their owners because the capital necessary for the thorough exploration of their merit has been lacking.

In the Kootenays, especially in the Slocan District, and in the Boundary section there are many of these dormant Crown Granted Claims. For the reason that they have been to some extent developed, they have been shunned by the prospector. In the last few years there has been a marked change in the attitude of the prospector and the small operator. A considerable number of the old Crown Grants have been taken under lease, given a further test, and there are cases where the results have been surprisingly gratifying.

For the benefit of the mining man who may be looking for such an opportunity as is offered by these idle "prospects" it may be explained that the law sets out that:

"When a Crown Granted mineral claim has been absolutely forfeited to and vested in the Crown under the provisions of this Act it shall be lawful for the Gold Commissioner for the mining division in which the claim is situated to grant a lease thereof to any person for the term of one year upon payment of the sum of twenty five dollars and upon payment of a further sum of twenty five dollars to grant renewal of the lease for further term of one year commencing on the expiration of the former lease but for no longer period."

At the end of the two-year period, if the lessee's work has had good results, he may proceed to obtain a Crown Grant in his own name.

Stewart.—A company has been formed in Seattle, known as the Eldorado Gold Mining Co., of which T. V. Wilson is president, to exploit the Eldorado Group of mineral claims, situated near the head of the Salmon Glacier, Portland Canal district. Three veins have been opened up on the four claims this summer by means of tunnels and open cuts. It is said that about 150 feet of tunneling has been done and that when work ceased on the 10th of September the faces of each was in high-grade ore. It is proposed to instal a concentrating mill with a capacity of 25 tons of ore a day and the ore mined this year is to be shipped for testing in order to obtain information as to the type of mill required. An aerial tram approximately 3,000 feet in length is planned to carry the ore from the mine to the mill. The present intention of Mr. Wilson and his associates is to ship in lumber next February in order that the work on mill and camp buildings may be well advanced by the summer.

Samples of striking ore have been arriving at Stewart from a number of comparatively new stakings. Some from the main vein of the Comstock Group, Texas Creek, are almost solid galena, with some grey copper and iron; others from a group of claims near Tide Lake, are composed of iron pyrites running about $8 in gold and, where there are quartz stringers, going as high as $200; and there are some specimens of steel galena from the Sunrise Group, August Mountain, near the head of Salmon Glacier.

Upper Peace River.— John D. Galloway, resident mining engineer at Hazelton, is visiting the Peace River country to inspect a number of mining properties. Among others he is looking over the Mount Selwyn Gold Claims, described as a large deposit of free-milling gold-quartz. Eastern Canadian capitalists are arranging for a test of 200 tons of the ore.

Lillooet.—The Whitewater District, northeast of Lillooet, has good prospects of developing into a fruitful mining field according, to W. A. Davidson, who has been opening up the Province claim. This adjoins the Windfall No. 1 and is under option to A. B. Trites, who is expected to take up the option. A tunnel has been driven for a considerable distance on the Province and while the main body of ore has not yet been struck, the indications are satisfactory.

Trail Ore Receipts.—Ore receipts at the Trail Smelter, for the week Sept 1st to September 7th totalled 3,046 tons. This brings the aggregate for the year up to date to 301,302 tons. The detailed shipments for the week follow:

	Tons
Alamo, Alamo	94
Bell, Beaverdell	44
Company Mines	2,319
Knob Hill, Republic Wn.	63
Lone Pine, Republic Wn.	162
Quilp, Republic Wn.	151
Silversmith, Sandon	141
White Water, Retallack	72
Total	3,046

Pioneer Metallurgist Dies.—E. H. Wedekind, for many years a resident of Spokane, died in California some weeks ago. He was the first superintendent of the Trail Smelter after its construction by F. Augustus Heinze about 28 years ago. Later he was engaged in mining operations with Spokane as headquarters. Over fifteen years ago he left for Nevada and other southwestern districts and San Francisco became his home.

Institute Meeting At Trail.—The British Columbia Division of the Canadian Institute of Mining & Metallurgy will meet at Trail on October 17th. The papers to be presented include: "A Symposium by Department Heads on the mining and metallurgical Practice of the Consolidated M. & S. Co." "Mining and Smelting operations at Anyox." by L. R. Clapp. "Recent Mining and Metallurgical Developments at Britannia", by W. M. Brewer; "The History and Progress of Mining in the Kootenays", by S. S. Fowler; "Undiscovered Mines of British Columbia", by Dr. W. L. Uglow; "Publicity and the Mining Industry", by C. M. Campbell; 'Small Scale Mining Operations and their Problems", by A. G. Langley; "The General Geology and Ore Deposits of the Grand Forks, Greenwood, Osoyoos, and Similkameen Mining Divisions", by P. B. Freeland; and "The Sulphur Industry", by F. W. Guernsey. Those attending will be given an opportunity to inspect the Trail Smelter.

Domestic Coke at Fernie.—The Crow's Nest Pass Coal Co. of Fernie and Michel is reported to have succeeded in producing a form of coke which will burn freely under a low draught such as that of an ordinary household furnace or kitchen range. It is said that this new fuel is made by partially treating the coal in the coke ovens; in other words by leaving incomplete the process used in the manufacture of metallurgical coke. The coke thus made is reported to be dustless, to burn readily, and to give good heat. John Todhunter, superintendent of coke oven operations at Michel, is confident that the fuel will become popular.

ALBERTA

The Drumheller Strike.—The trouble between employers and employees of the Drumheller Collieries is reported to be nearing a settlement. The men have decided to return to work and to submit the dispute to an independent tribunal for adjustment. Hon. James Murdock, Federal Minister of Labor, is expected to be named to arbitrate and his decision will be binding on both parties. William A. Sherman, president of District 18, U. M. W. of A., has been busy for several weeks in an effort to get the men back to work It was the decision of the U. M. W. of A. that the miners were violating their agreement with the Western Coal Operators' Association in walking out and, when they refused to return, the charters of the U. M. W. of A. Locals at Drumbeller, which were involved in the strike, were revoked. It was at a mass meeting following this announcement that the men agreed to arbitration. The men charge discrimination against certain men, notably James Conroy, who was employed at the Higrade Mine, and claim also that they have the right to establish an O.K. list system whereby all miners hired would have to obtain a slip from the local union before going down a pit. The legality of this propesal will have to be considered.

New Colliery Project.—The Alberta Carbon Coal Co. Ltd. has been formed for the exploitation of 2,640 acres of coal lands in the Carbon District, twenty miles west of Drumheller. The seam to be developed is reported to be five feet wide and to be capable of producing some 10,000,000 tons of coal. The company is capitalized with a share capital of $500,000 and $100,000 first mortgage eight per cent gold bonds. H. Ransford is the president and W. P. Hinton, former general manager of the G. T. P. is a director.

Extension of $7.00 Freight Rate to Ontario.—As a result of a discussion between Premier Ferguson of Ontario, and Sir Henry Thornton, of the Canadian National Railways, it has been announced that 10,000 tons of Alberta coal will be transported to Ontario at the rate of $7 a ton. This concession, however, extends only to the end of October. The coal is to be distributed by the Province to such dealers and municipalities as make application to the Minister of Mines of Ontario while it lasts. A survey shows that Ontario has so far received 48 per cent. of a normal winter's supply of anthracite and 120,000 tons more than was on hand at this time last year. With the resumption of work at the American mines no serious shortage is anticipated.

This action can only be considered as an emergency measure. In a recent statement J. M. Dalrmple, vice president of the C. N. R., said that the tariff on coal from Alberta to Ontario points had been advanced to $12.50 a ton. He explained that a limited amount had been carried at $7 a ton for experimental purposes. The period fixed having passed, the rate had been placed again on a commercial basis. Another railway official was quoted as saying that Alberta coal could not hope to compete in Ontario with the Pennsylvania product because of the long haul and that, anyway, it had not proved a satisfactory substitute for the anthracite.

Judging from the attitude of Jesse Gouge, president of the Western Canada Coal Operators' Association, the hope of finding a permanent market in Eastern Canada for Alberta coal has not been abandoned. He says that negotiations are afoot for low freight rates on western coal after January of next year, that the experiment of shipping Alberta coal to Ontario was successful, as a repeat order came for every car dispatched, and that with fair rates, — anything from $7 to $9 a ton, — —Alberta operators could compete. He said that $9 would be the maximum, and $7 the best, and anything between the two would be welcome.

R. M. Young, commissioner of the Western Canada Coal Operators' Assn., declares that there is no intention to drop the fight, notwithstanding the geographical difficulties and that, sooner or later, the Association will get what is wanted.

THE NATURAL RESOURCES INTELLIGENCE SERVICE

A new catalogue of publications, just issued by the Natural Resources Intelligence Service, shows a number of useful maps, reports, and pamphlets, which that organization has prepared for the information of the investor, for the assistance of those engaged in commerce and industry, and for the guidance of the prospective settler. Economic maps illustrating progress along agricultural, commercial, and industrial lines; geographic maps of Canada, also the various provinces and districts; and interesting reports based on investigations made by the Service, comprise the collection of several hundred publications, that has been published to date.

The Service is a branch of the Department of the Interior, whose function it is to provide a central bureau of information respecting Canada's natural resources — a need to which public attention has frequently been drawn. Its work embraces a very broad field, necessitating the consolidation of much data gleaned from the evidence of explorers, corporation records, scientific and technical journals, and the reports of enquiries carried on by special commissions, universities, and other agencies. As the gathering and assembling of such information is only a means towards an end, it must be put into such form as to shed light upon the practical problems of development enterprise. Consequently much of the data is recast and

transferred to standardized maps, reports, and pamphlets, which enable related groups of facts to be furnished with the least possible delay.

Special importance has been attached to the preparation of geographic and economic maps, as a well-designed map is the most effective method for recording many classes of information which if handled in any other manner could not be studied with the same ease or effect. For instance a series of maps will convey more quickly and clearly than fifty pages of text, a correct appreciation of the distribution of Canada's resources, the main features of the coal situation, the problem of marketing the wheat crops of western Canada, or opportunities for establishing a new industry. As a consequence the Service publishes regularly a standard set of geographic maps, a series covering the land situation in the Prairie Provinces, Resource Maps of the Dominion and numerous publications along similar lines, as set out clearly in the catalogue of publications, just issued and obtainable on request.

Research in the United States

United States Federal and State Governments appropriated $57,000,000 for research in 1919-20.

The great work of Coolidge and Langmuir in developing the Nitrogen tungsten lamp now extensively used, has reduced the consumption of electric current to one-seventh of the former quantity.

PROVINCE OF QUEBEC

MINES BRANCH

Department of Colonization, Mines and Fisheries

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, etc.

MINISTER OF COLONIZATION, MINES AND FISHERIES, QUEBEC

MINER'S CERTIFICATES. First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. The price of this certificate is $10 and is valid until the first of January following. This certificate gives the right to prospect on public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres.

WORKING CONDITIONS. During the first six months following the staking of the claim, work on it must be performed to the extent of at least twenty-five days of eight hours.

SIX MONTHS AFTER STAKING. At the expiration of six months from the date of the staking, the prospector, to retain his rights, must take out a mining license.

MINING LICENSE. The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cents an acre per year, and a fee of $10.00 on issue. It is valid for one year and is renewable on the same terms, on producing an affidavit that during the year work has been performed to the extent of at least twenty-five days' labour on each forty acres.

MINING CONCESSION. Notwithstanding the above, a mining concession may be acquired at any time at the rate of $5 an acre for SUPERIOR METALS, and $3 an acre for INFERIOR MINERALS.

The attention of prospectors is especially called to the territory in the North-Western part of the Province of Quebec north of the height of land, where important mineralized belts are known to exist.

PROVINCIAL LABORATORY. Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY, 228 ST. DENIS STREET, Montreal, for the determination, assays and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensure results of undoubted integrity and reliability.

The bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of the Province, on application addressed to

HONORABLE J. E. PERRAULT,

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

BRITISH COLUMBIA

The Mineral Province of Western Canada

Has produced Minerals valued as follows Placer Gold, $76,542,203; Lode Gold, $109,647,661; Silver, $59,814,266; Lead, $51,810,891; Copper, $170,723,242; Zinc, $24,625,839; Coal and Coke, $288,289,565; Building Stone, Brick Cement, etc., $36,605,942; Miscellaneous Minerals, $1,358,839; Making its mineral production to the end of 1922 show an

Aggregate Value of $734,259,619

The substantial progress of the Mining Industry of this Province is strikingly exhibited in the following figures, which show the value of production for successive five-year periods: For all years to 1895, inclusive $94,547,241; for five years, 1896-1900, $57,605,967; for five years, 1901-1905, $96,509,968; for five years, 1906-1910, $125,534,474; for five years, 1911-1915, $142,072,603; for 5 years 1915-1920, $189,922,725; 1921, $28,066,641; for the year 1922, $35,158,848.

Production During last ten years, $339,280,940

Lode-mining has only been in progress for about twenty-five years, and not 20 per cent. of the Province has been even prospected; 300,000 square miles of unexplored mineral bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than those of any other Province in the Dominion, or any Colony in the British Empire.

Mineral locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full information, together with Mining Reports and Maps, may be obtained gratis by addressing

Modern Air Compressors

Modern air compressors have certain features which largely account for their high efficiency and uninterrupted performance.

Enclosed frame construction with automatic flood lubrication of main bearings, crank and crosshead pins and crosshead guides, resulting in a clean, easy-to-take-care-of machine and smallest oil consumption.

Small floor space and foundation because of compact self-contained design and correct distribution of forces.

Automatic and reliable regulation for loading and unloading the compressor according to the air volume and pressure required.

Admission to and discharge of air from cylinder with least friction loss due to the use of automatic Plate Valves with large and liberal free air passages.

Class "ER" Belt Driven and Class "FR" Steam Driven Compressors have all these features and many more. Every detail of design and construction has been worked out with one chief idea in mind—a compressor which will actually deliver the greatest number of cubic feet of air per dollar spent for power, upkeep and attendance.

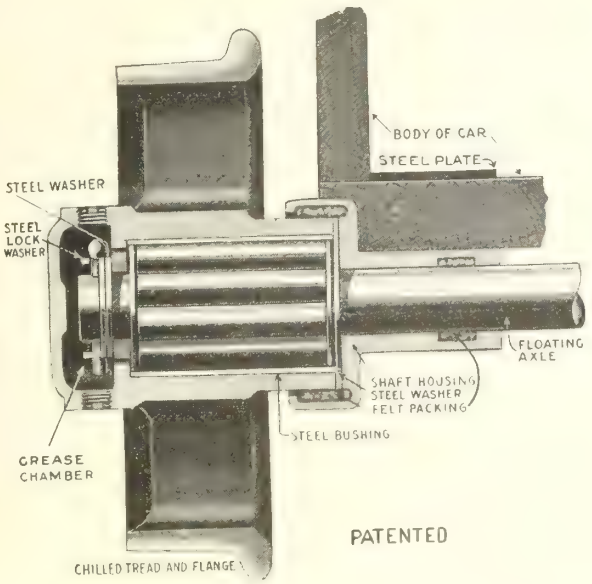
ROLLER BEARING MINE CAR WHEELS.

SPECIAL TOUGHENED CAST STEEL OR CHILLED CAST IRON.
A MECHANICALLY CORRECT ROLLER BEARING.

MADE IN SIZES
FROM
10 DIA. TO 24 DIA.
ANY GAUGE



THIS CONSTRUCTION PERMITS AXLE TO REVOLVE SUFFICIENTLY TO DISTRIBUTE WEAR AND AVOID FLAT WEARING AXLES.

THE HUB OF THE WHEEL IS LINED WITH A RENEWABLE HARD STEEL BUSH.

ROLLERS AND AXLES OF SPECIAL HIGH GRADE STEEL. EASY TO RENEW THE GREASE WHEN REQUIRED.

MANUFACTURED IN CANADA BY

THIS CRANE PIPING CONTRIBUTES TO THE SAFETY AS WELL AS THE WORKING EFFICIENCY OF A LARGE CENTRAL STATION

INSURING SAFE HIGH PRESSURE PLANTS

Meeting the need of the modern power plant for piping equipment to handle high pressure superheated steam, Crane Ltd. has produced a complete line of valves, fittings and steam specialties of cast-steel and monel metal. The use of these materials overcomes the "growth" or permanent expansion encountered with cast iron, malleable iron or semi-steel units which are subjected to wide temperature variations. Crane cast-steel equipment retains its original size and strength under the most severe conditions, insuring permanently tight connections and maximum safety.

Ontario's Minerals

PROVINCE OF ONTARIO

Hon. CHARLES. McCREA, Minister. DEPARTMENT OF MINES *Thos. W. Gibson*

Mineral Areas

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favourable for the occurrence of minerals 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver veins of Cobalt, Gowganda and South Lorrain occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

Economic Minerals

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario: — actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluorspar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, Portland cement, brick and tile, meet every demand.

Mineral Production

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1922 to be worth $62,202,169, of which the metallic production was $38,190,711.

The following figures show the growth of Ontario's mineral industry by five-year periods since 1891 when a Bureau of Mines was first established.

Year.	Value.	Year.	Value.
1891	$4,705,672	1911	$41,976,797
1896	5,235,003	1916	65,303,822
1901	11,831,086	1918 (Maximum war output)	80,308,972
1906	22,388,383	1921	48,128,387
	Dividends.		

Dividends and bonuses paid to the end of 1922 amounted to $28,096,699 for gold mining companies, and $86,238,185 for silver mining companies or a total of $114,334,884.

Mining Regulations

A miner's license costs $5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of $2.50 or $3.00 per acre, depending on location in unsurveyed or surveyed territory.

Assay Office

The Provincial Assays Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

A Bank That Is Always Near

The mining engineer — moving as he does from place to place — must needs utilize a bank which has branches conveniently located in mining centres.

The Imperial Bank, with 192 branches throughout Canada and with special concentration in mining districts, offers distinct advantages to those engaged in the mining industry. Patrons of this Bank are never far from their bank accounts, no matter to what part of the Dominion they may go.

Why not ensure adequate banking facilities by depositing your funds with this Bank?

IMPERIAL BANK OF CANADA

The Largest Producers Of Steam-Distilled Pine Oils

The Hercules Powder Co.'s three plants for the production of steam-distilled pine oil now comprise two-thirds of all the plant capacity available for this product.

Absolute chemical control of all operations is required at these plants. We realize the necessity for uniformity in successive shipments of any flotation oil. Our naval stores organization is accomplishing this result.

No effort is spared to make Hercules Pine Oils the best from the standpoint of flotation operators who judge an oil by the profits per ton of ore treated.

A TRUST

Last month one of the syndicates operating in the gold district of northwestern Quebec paid $2,000 into the provincial treasury on account of the tax on mining claims of 50 cents an acre due six months after staking. The syndicate has spent several times this amount in prospecting its claims during the season now drawing to a close, with results that well warrant this further expenditure. They have paid the tax cheerfully, convinced that they will discover sufficient gold on the land so held to recoup their total expenditure many times over.

Under the present administration of Quebec's income from its mineral lands, $1,800 out of this $2,000 will be spent for purposes other than mining; only $200 will be spent for the upkeep of the Bureau of Mines, for geological surveying, for roads into new mining camps, for trails to assist prospecting, for the maintenance of recording offices and for the innumerable additional public services that stimulate, aid and direct mineral development. Is this fair? We put the question to those responsible for formulating the policies and administering the laws that govern this expenditure.

The case cited is typical of dozens of others. The province will derive this year a handsome revenue from its new gold area. Those who hold claims are confident, not only of discovering payable deposits on their land, but of the good faith of the provincial Government. An adequate transportation service is required, not only to aid the intensive prospecting that must precede most discoveries, but also to assist in the underground development of these properties. Private owners have demonstrated their faith in the district by large expenditures. Part of their money is now held in trust by the Government as taxes. This tax has been levied, not on a going concern such as an operating mine, but on raw prospects. It would be a gross breach of this trust were the money spent otherwise than on roads or other facilities that will aid the prospective mines to reach the stage of profitable operation.

We are confident that the Government authorities in Quebec require merely to realize these facts in order to ensure that appropriate action will be taken. For almost a whole generation there has been no marked advance in the province's mineral industry, apart from the gradual and highly satisfactory growth of asbestos production. Consequently the legislators at Quebec are not accustomed to the idea of fostering and aiding a new mineral development; they have seen only evanescent "booms" during their régime; to watch the advent of a new mining camp is a new experience.

The first season's work indicates that there will be not one, but several gold mines in northwestern Quebec. Until these mines become established upon a paying basis, and thereby become liable to taxation like any other profit-making concern, it is incumbent upon the Government at Quebec to return to the district, in the form of roads and other facilities, at least the equivalent of the sum collected from it in taxes.

FIRE PREVENTION

This is fire prevention week — and likewise the anniversary of the conflagration that swept along the Temiskaming and Northern Ontario Railway last year, destroying Haileybury and making thousands homeless. The fire rangers have been withdrawn for the season — whether prematurely or not this year, we are unable to say. There are already some press dispatches telling a story of slash-burning such as preceded last year's fire. We trust the situation is, this year, well in hand.

Fire Control, published by the Department of Insurance in Ottawa in the interests of fire prevention, prints a "Fable for Builders" in its current issue, which applies equally well to lumbermen, Government officials, prospectors, settlers and any and all whose negligence with fire might endanger the lives of others. Here is the fable:

"Last summer a Good Citizen of a certain town, not over a hundred miles from almost everywhere, built a wooden house for a woman and her children. He built the chimney of brick because he had to do so. The chimney was able to stand alone so he did not have to prop it with wood. But the floors of the house would not stay up without props. The Good Citizen saved a dollar by using the chimney as a support for the floors. He nestled the ends of the floor joists nicely into the brick of the chimney. He then covered up the job and got his money.

"The rains fell and the winds blew in the most Biblical manner, and winter came after its usual fashion. The chimney settled a little and there was a tiny crack.

"One morning the woman woke up with fire all about her. She tried to get to her children. If she got to them, no one ever knew it. The Good Citizen

who built the house was not arrested for manslaughter. He is still building other houses of the same kind for other women and children.

"He makes his living by it."

SAFETY IN GOLD MINING

To the first well informed traveller in an unexplored land belongs the privilege of scanning its hillsides for evidences of mineral wealth. Some of the world's outstanding mines owe their discovery to so simple a search. Even at this date, when the larger part of our globe's land surface has been subjected to a close scrutiny by the geologist and the prospector, there remain a few vast tracts whose hillsides remain to be seen by a mining man.

Such an area is now being explored in central Africa, the present and prospective mineral belt extending through the eastern part of the Belgian Congo, across the equator into the southern Sudan, on the Nile watershed. We quote today on another page a brief description of this area by Mr. Robert Williams, who is concerned in directing its exploration and mining development. The vast scale of both the exploratory and the subsequent mining operations, and withal the simplicity and directness of the principles upon which the plan of action is based, induce one to adopt for a moment the continent-wide, or world-wide, point of view which alone can make such an undertaking successful.

Mr. Williams is fortunate in having gained his experience in mining on the vast reefs of the Rand. In addition, he was pupil to that master builder of industries and Empire, Cecil Rhodes. Consequently he was well prepared to map out a plan of campaign for the development of the Belgian Congo, when the first explorers brought back word of copper ore abundantly available to the natives and rumours of other mineral riches. He secured the coöperation of British investors with the Belgian owners of the land and with the aid of the requisite technical men located the ore zones, proved their size, built railways, opened a colliery, established smelters and arranged overseas markets, all within a marvellously short term of years. This was in the Katanga field. The cycle of events will be repeated further north, in British territory, provided the mineral resources disclosed by the present prospecting warrant it.

The copper ore of the Katanga is not only found in vast quantity, but is unusually high in grade. Already the smelter at Elisabethsville is a notable source of the world's supply of copper, and its operations are only well begun. The Katanga seems destined to share with the United States and Peru the distinction of providing copper for the world at large. If its reserves of high-grade ore should continue to increase as during the last few years, the mooted world shortage of copper and the consequent high prices will be postponed indefinitely.

Last year the phenomenally rich uranium ores of the Katanga captured the world's market for radium at one swoop. The thousand-mile haul to the sea board had little effect in reducing the value of the ore. In a day, almost, the United States was robbed of what had seemed a secure monopoly of the world's radium supply.

It will be interesting to note what other metal central Africa will succeed in adding in large measure to the world's output. Tin is being produced already, and the output of cobalt might possibly grow to such dimensions as to reduce Canada's predominance in its supply. None can tell what additional treasures will be disclosed during the next few years.

Meantime it is highly satisfactory to know that the larger part of Canada's new mineral development is of such a nature as to be unaffected by the output in other countries. Most of the growth is in the gold and silver fields. It will be a long, long time before there is any glut in the market for gold, and the prospects for silver are bright. With regard to the base metals, we cannot hope to do a great deal more than supply our own needs, with a modest amount for export. If the slow process of discovery resulting from the soil and forest growth covering most of our mineral areas should allow us to develop mines of copper, lead and zinc to meet the demands of our growing population, we shall do well. Due to the phenomenal deposits of the Sullivan mine, zinc is a lap ahead in the race, and a substantial part of the electrolytic zinc made at Trail is exported. We have been lucky with nickel, too, and the advantage conferred by the richness and size of the Sudbury deposits is likely to remain with us. Ores of aluminium and tin, which we lack at present, would be a welcome addition to our list, and the slim output of platinum would stand augmenting.

All told, it is a fortunate thing for Canada that our principal advance in mining today is gold, with its non-competitive market. In the gold fields prospectors can pursue their search and investors can put up their capital, secure in the knowledge that no discoveries in other parts of the world will either rob them of their market or reduce the price of their product.

RADIO AIDS MINING

Radio is beginning to have a place of some importance in the mining industry. At first it offered a lucrative market for galena and other crystallized minerals for use in receiving sets. Now it is serving the industry directly.

While on a trip fifty miles from the railway in northern Quebec a few weeks ago we learned the ...

sults of the recent famous (or notorious) fistic encounter, round by round, by radio. A few days later, on a Sunday, we were interested to pick up a sermon delivered in Philadelphia. It began in the orthodox fashion with a text, but then proceeded to the life history of George Washington and a review of the American Constitution, at which point we shifted to a concert. There was no mail service at this camp, but the operator kept in touch with world affairs, commencing with baseball, through the radio each evening.

Recently the broadcasting stations have included educational talks in their programmes. Short, non-technical expositions of various features of the mining industry are included. One such talk, broadcasted from the Marconi station in Montreal recently, gave a very good resumé of Quebec's asbestos industry. It was estimated that 200,000 listeners heard it. We would judge that this is a very effective means of enlarging the public's knowledge of the little-known mining industry, particularly because no inspired paragraphs and unwholesome stock advertisements can be sandwiched into the radio talk, as is done invariably in the general public's chief source of mining news, information and misinformation, the daily papers.

Some of the radio receiving apparatus now available is so compact and light and so reasonable in price that it is available even to prospectors, who are usually impecunious and must travel light if they are in earnest about their work. Thus the loneliness and solitude of even these pioneers of the mineral industry can now be alleviated by the use of a radio set.

Mining camps and mining prospects have long been notorious for their isolation. This was relieved somewhat by the telegraph, and still more by the telephone; but the cost of the wires often was prohibitive. Now comes radio to provide a link with the outside world that costs no more than a canoe or a blacksmith forge. Truly, civilized man has conquered the wilderness.

NEW MAP OF LAKE ATHABASKA

The Geological Survey, Ottawa, has issued a map (publication No. 1991) of Lake Athabaska, on a scale of 8 miles to the inch, which shows the geology of the shores on an accurate geographical base.

COLD DRIP AND END OF STEEL

A little cold drip runs down my neck,—
A little cold drip gets bigger, by heck!
Sing ho, for the out of door life!
It runs down my spine and encounters my toes,
Now all of me's wet and most of me's froze:
Sing ho, for the out of door life!

A little cold bacon lies in the pan;
The grub is enough to sicken a man:—
Sing h-ll, for the out of door life!
The fire is out and the blankets are wet;
The little cold drips are dripping yet:—
Sing h-ll, for the out of door life!

A little grey ticket is in my jeans;
I'm fed right up to the neck on beans:—
Sing ha, for the end of steel!
A dining-car menu's the goods for me,
And this is the last of the woods for me,—
Praise be, here's the end of steel!

J. C. M.

Natural Gas and Petroleum Resources of Western Canada

The Manufacture of Carbon-Black—I

By NEWTON W. EMMENS

On August 25th, 1923, Regulations were established by Order-in-Council permitting the use of natural gas for the manufacture of carbon-black in localities where there is no immediate or reasonably prospective market for the gas for domestic or industrial purposes. This is an important step in the right direction, which will result in the building up of an industry in Alberta and other places where there are large supplies of natural gas remote from present or immediately prospective centres of population, and will make profitable those ventures in the search for oil that have resulted in the discovery of natural gas only; which ventures, if permission to utilize the gas in the manufacture of carbon-black and other by-products had been withheld, must have resulted in loss.

New Carbon-Black Regulations

The Regulations are well considered and take care of the interests of the present and future population adjacent to the gas fields as well as those of the operators. The outstanding provisions are:

Natural gas can be utilized for the manufacture of carbon-black only where the producing field is too far distant from a centre of population to make the piping of the gas to that centre a reasonable proposition.

If the gas contains gasoline in commercial quantities, the gasoline must be extracted and saved before the gas is burned to carbon-black.

If, at some future time, after the factory for the manufacture of carbon-black has been established and is in operation, any community or company holding a franchise to supply natural gas to any centre of population constructs a pipe line to the wells supplying the carbon-black plant, such holder of the franchise shall be entitled to purchase the amount of gas necessary to supply the centre of population up to the capacity of the wells, and the carbon-black plant will be allowed to burn only the surplus gas for the manufacture of carbon black.

Gasoline to be Extracted

The provision requiring the extraction of gasoline from the gas before using it for other purposes is a wise one; but the question as to what constitutes gasoline in commercial quantities is one that, from the experience of the writer, cannot be decided off hand, because it depends wholly upon the price that can be obtained for the gasoline, f.o.b. tank cars or in pipe line at the works and the amount of gas treated daily. In some instances it would be a profitable undertaking to treat natural gas containing as little as one-tenth gallon (0.64 Imperial pints) of gasoline per thousand cubic feet, and in others it would not pay to treat gas containing less than three-tenths gallons (1.92 Imperial pints). The type of plant and the process used is also an important factor in determining this point. It has been proved by actual experience that a gas from which three hundred gallons of gasoline was recovered per million cubic feet of gas, treated by one process, yielded five hundred gallons per million cubic feet when using a different system of extraction.

While the regulations do not specifically state that the gasoline (when existing in commercial quantities) contained in the natural gas must be extracted and recovered before the gas is sold for domestic and industrial purposes, this also should be done, not only because the gasoline is more valuable as a liquid for automotive purposes, but because it is a source of much trouble in a pipe-line, due to its condensing, particularly in cold weather, collecting in the low places in the line, and obstructing the free flow of the gas. There is another advantage also, which will be fully appreciated by operators supplying communities with natural gas through long pipe lines, in removing the gasoline from the gas. This is that the water present in the gas both in the form of vapor and as water is also removed. Water in the gas is a source of much trouble, due to its condensing in the pipe lines, collecting in the low parts of the line and freezing in cold weather.

Heating Value of Residual Gas

Some persons are under the impression that taking the gasoline vapor from natural gas materially reduces the heating value of the residual gas. This is not so, as has been proved by the investigations carried out by the U. S. Bureau of Mines, the results of which were published in Technical Paper 253. The following figures taken from this publication are of interest in this connection, giving as they do the B.t.u. of the untreated gas, the B.t.u. of the residual gas after the removal of the gasoline, and the amount of gasoline in gallons (U.S.) recovered per thousand cubic feet of gas treated:

B.t.u. value of intake gas	B.t.u. value of residual gas	Loss in B.t.u.	Gallons of gasoline recovered per 1,000 cu. ft. of gas
952.0	939.0	13.0	0.115
1,098.2	1,048.2	28.2	0.234
1,148.8	1,087.0	61.8	0.573
1,420.6	1,170.6	250.0	1.580

The percentage loss in heating value of the gas ranges from 1.76 to 17.60 and is so small that it requires delicate laboratory apparatus for its determination. It is interesting to note that the heating value of the residual gas showing the greatest loss, namely 250 B.t.u., is still very much greater than that of the intake gas which contained a little over one-tenth gallons of gasoline per thousand cubic feet. The heating value of artificial gas such as is used in a great many cities is between 500 and 600 B.t.u., so that 1,000 cubic feet of natural gas with its contained gasoline removed equals from 1,500 to 2,000 cubic feet of the manufactured variety, for heating, cooking and power purposes—a matter of no small importance to the average consumer.

Unfortunately, however, the market for natural gas in east central Alberta for domestic and industrial purposes is very limited and there is no prospect of the population being able to utilize even a small percentage of the available supply for many decades to

come. It is therefore necessary to consider other uses to which this gas can be put profitably. One of these is in the manufacture of carbon-black.

Characteristics of Carbon-Black

Carbon-black is the name given to that pure, intensely black, flocculent form of carbon made by the burning of natural gas with a smoky flame by admitting insufficient air for complete combustion. It has properties that are unobtainable in any other black pigment that has been produced hitherto and it fills a place in the arts that cannot be taken by any other known substance. The more important of these properties are: unique brilliancy and intensity of color, complete freedom from hard and gritty particles, great covering power when made into ink by mixture with oil and chemicals, reinforcing properties when added to rubber, and its extreme minuteness of division. This last is better understood when we realize that one cubic inch of carbon-black contains 1,905,000 square inches of surface, or about one-third of an acre, according to the investigations of W. F. Weigand, the American rubber chemist.

Uses and Markets

The industrial uses of carbon black are: in the manufacture of printers ink; the rubber industry, including automobile tires both pneumatic and solid; stove polish; shoe polish; typewriter ribbons; carbon paper; phonograph records, paints for ships and structural iron; carriage cloth; cameras; coloring leather; electrical insulators; celluloid; cement colors; drawing inks; artificial stone; tile; tarpaulins; buttons; etc. There is a good export demand from France, England, Japan and China, and so soon as Germany, Austria, and Russia get back on their feet they will be in the market for large quantities. To the Canadian producer the markets of Great Britain and other members of the British Empire. and of Japan and China, offer exceptional opportunities for building up an important business that will absorb all the carbon-black produced in excess of that required for home consumption.

Yield from the Gas

The quantity of carbon-black obtained from each thousand cubic feet of gas burned depends upon two factors; first the composition of the natural gas, second the particular use for which the black is intended. The average yield is from one-half pound per thousand cubic feet of natural gas from Wyoming, up to one and eight-tenths pounds per thousand cubic feet of natural gas in Kentucky, according to the information contained in the chapter on Natural Gas in the "Mineral Resources of the United States," issued by the Department of the Interior of that country, for the year 1921.

The variation in yield of carbon-black due to the difference in composition of natural gas is well exemplified in the following extract from a letter from N. B. Burr of the Columbia Carbon Co., Williamsport, Pa., which appeared in *Chemical & Metallurgical Engineering* on July 25th, 1922. Mr. Burr says:

"Actual experience of our Company has proved that the identical factory, when moved to a new location and using leaner gas, may show a diminution in yield of as much as 30 per cent. This is, of course, due to the difference in the composition of the gas. The following analyses of gas from three different states will illustrate;

	No. 1 gas percent	No. 2 gas percent	No. 3 gas percent
Methane	80.5	94.12	46.45
Ethane	18.0	3.44	43.10
Carbon dioxide	0.0	0.40	0.96
Nitrogen	1.5	2.40	9.49

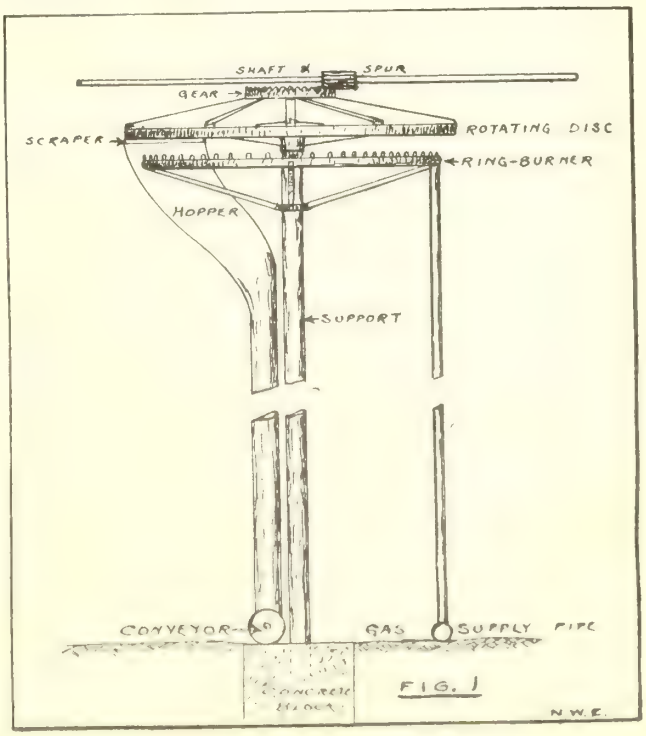
"A standard type factory, operating on No. 1 gas, averaged 1.4 pounds per thousand cubic feet. The same factory, removed to a new location, using No. 2 gas, produced only 0.9 pounds per thousand. A factory of the same type and design, similarly equipped and operated, yielded an average of 1.75 pounds from No. 3 gas."

The No. 2 gas contained 38.8 pounds of carbon per thousand feet of gas, which with a recovery of 0.9 pounds in the form of carbon-black, showed an efficiency of 2.66 percent. The No. 3 gas contained 44.3 pounds of carbon black per thousand feet and yielded 1.75 pounds, an efficiency of 3.95 percent. The No. 1 gas containing 39 pounds of carbon per thousand feet with a recovery of 1.4 pounds shows an efficiency of 3.58 percent.

An Opportunity for Research

While this efficiency is admittedly low, no process has yet been devised that will obtain a greater yield of carbon black of the required quality. Some years ago attempts were made to decompose natural gas in a retort under intense heat in the presence of a catalyst, and yields of from 8 to 10 pounds of carbon were obtained per thousand feet of gas treated; but this material was not carbon-black as that substance is known to the trade; it was a heavy gritty powder, deficient in color and lacking all the properties that make carbon-black so useful; in fact, a jobber to whom the material was submitted stated that it might do to blacken the face of a minstrel, but it was most certainly good for nothing else.

The Bureau of Mines of the United States has done much valuable work in the endeavor to find a process that will obtain a better yield of carbon-black of the required quality from natural gas, but nothing



commercial has yet been worked out. Of these experiments more will be said at the end of this article.

There are four processes in commercial operation for the manufacture of carbon-black. They are the small disc, channel, large plate, and roller processes. The chief difference in these processes is in the shape and size of the surfaces upon which the flame impinges and deposits its carbon-black, and in the speed at which the depositing surface moves over the flame. A brief description of these processes follows:

Small Disc Process

This process is the invention of A. R. Blood, who obtained a patent for it in 1883. The same process, with a few improvements in details, is used extensively at the present time.

The disc (see Fig. 1) upon which the carbon-black is deposited is made of cast iron. It is 36 to 42 inches in diameter and has a 6-inch face. This disc is set upon the top of an upright, made from a length of pipe of the required size, into which is fastened an axis upon which it is rotated, at the rate of one revolution in fifteen minutes, by means of a suitable gear and pinion. When set up it much resembles a flat umbrella.

Below the disc are arranged lava-tip burners set in a ring made of ¾ inch pipe 28 to 32 inches in diameter, according to the size of the disc used. This ring contains from 18 to 24 tips and is supported by the gas supply pipe together with braces from the upright.

The scraper for removing the carbon-black as it is deposited upon the under surface of the disc is in continuous contact therewith, and immediately below it is a hopper to collect the carbon-black as it falls from the disc and to conduct it to the conveyor on the floor between the rows of burners. Fig. 1 is a sketch of one of these rotating-disc burners set up.

These burners are set in rows of 21 each, with two, but more often four, rows in a building. Between the rows on the floor is located a spiral conveyor, made of sheet iron, 8 inches in diameter. At the discharge end each conveyor is connected, by means of suitable piping, with the main conveyor system of the plant, which collects all the carbon-black from the burner-buildings and conveys it to the bolting and packing house. (See Fig. 2.)

Each row of discs has a separate drive shaft, which is rotated by means of a pinion from a gear on the main power shaft in the alley between the buildings.

The burner-buildings are of sheet iron fastened to a frame work made of ⅜" by 1½" x 1½" angle iron. They are 15 to 20 feet wide and from 95 to 110 feet long. Along the ridge of the building openings are provided for the escape of the gases of combustion. These openings are covered with a movable slide so that the size of the opening can be changed and the draft regulated as may be required by atmospheric conditions. In the more recent plants the burner-buildings have chimneys, provided with dampers, set at intervals along the ridge. These have proved more efficient, particularly in sections where the climate is cold in the winter. Along the base of the buildings slides are provided to control the amount of air admitted to the burners, while a door at each end with two on either side furnish means of access to the interior.

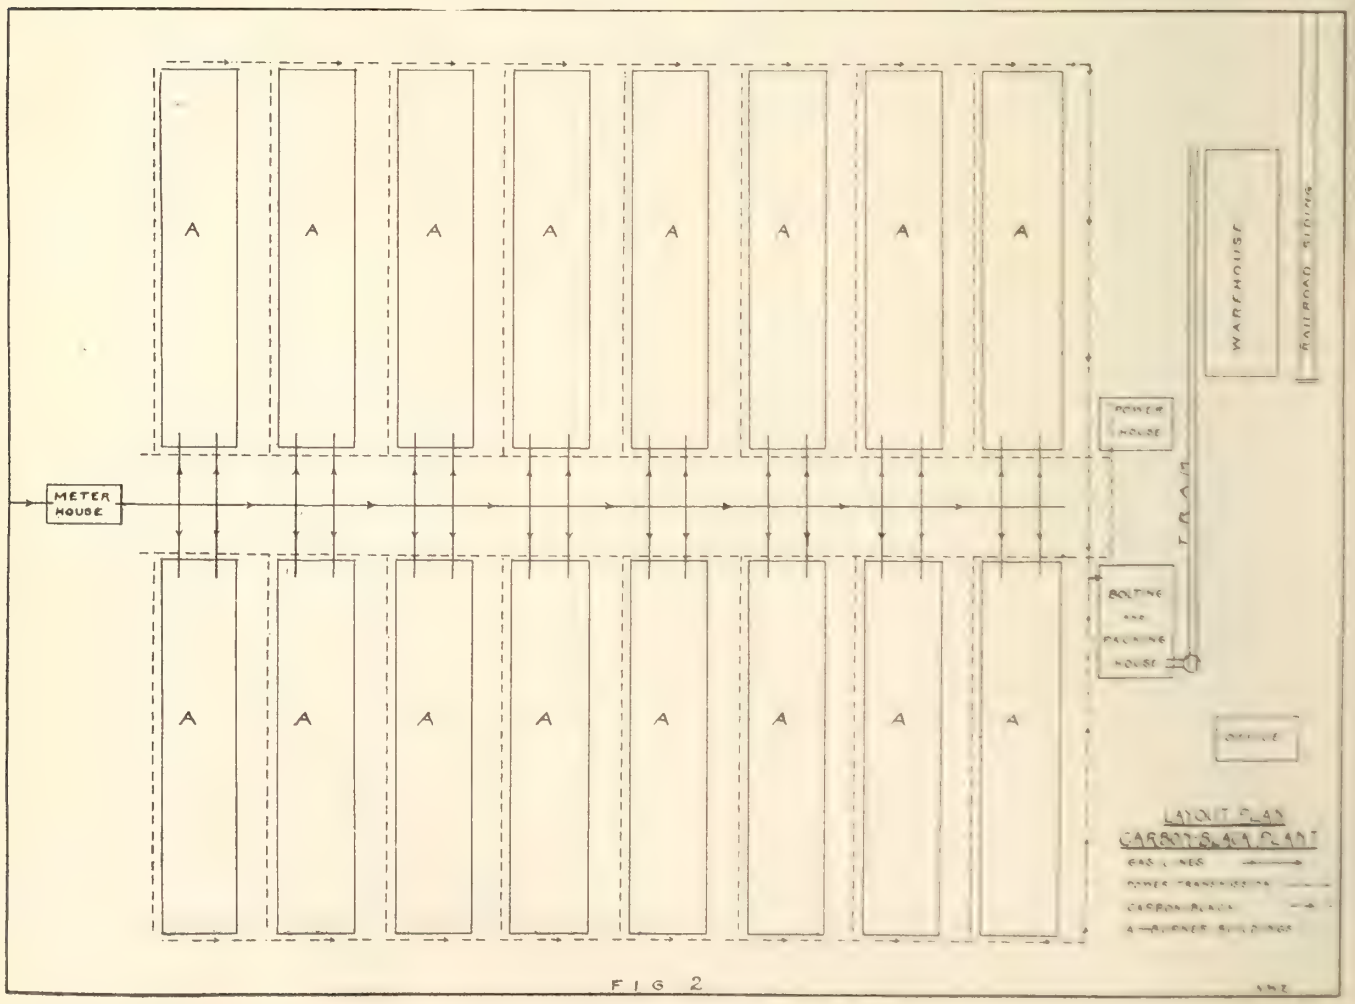


FIG 2

The buildings are arranged in rows on each side of, and at right angles to, a road. The distance between rows and individual buildings depends much upon the climate of the locality where the plant is built. In a warm section these distances are greater than in a cold, but it is usually from 5 to 10 feet between buildings and 15 to 20 feet between rows.

From the burner-buildings the carbon-black is conveyed, as previously stated, to the bolting and packing house, where it is delivered to a bucket elevator that elevates it to the first set of bolting machines, which remove any coarse, hard particles, dirt and scale. From here the carbon-black is passed through a second bolting machine having a finer screen and from these to the storage bins.

The bolters consist of a steel wire screen fastened to the end of a sheet iron cylinder enclosed in a box made of galvanized iron. A shaft to which is attached a spider with six arms, each of which carry two fibre brushes, revolves slowly within the bolter and forces the carbon-black through the screen. The material that will not pass through the screen is removed from time to time and thrown away. The first set of bolters have a screen of eight meshes to the inch and the second set one of fifty or sixty meshes.

The storage bins are made of galvanized iron and vary in size according to the ideas of the operator. Usually they have a capacity sufficient to take care of two or three days' production of the plant so as to avoid a plant shut-down in the event of trouble in the packing or shipping department; also in order to take care of the output over Sundays and holidays when the packers do not work. The storage bins have a conical bottom which is connected with the packing machine by a spout, which latter is provided with a gate to control the flow of carbon-black or to shut it off entirely.

The packing machine used for carbon-black is similar to that used at sugar refineries and consists of an auger inside a metal tube, which presses the carbon-black into a heavy paper bag. The machine is so designed that when the packer is stopped for changing bags the flow of the free-running carbon-black is arrested and there is no leakage past the auger. The machine is set so as to pack a uniform amount into each bag, which for domestic trade is 12½ pounds, or a quarter barrel. For export, fifteen pounds is put in each bag. The movement of a lever starts the machine and it stops automatically when the bag is filled with the prescribed amount. The time required to fill a bag is about fifteen minutes.

From the packing house the bags of carbon-black are taken to the warehouse, which is located on the railroad siding, or other main line of transportation. Carbon-black intended for export is packed in iron-bound boxes containing twelve to fifteen bags; that intended for domestic consumption has a second paper bag put over the first and is loaded into box cars in a similar manner to flour.

A carbon-black plant is divided into units, each of which is complete in every detail and can be operated independently of any other. The units consist of 16 to 20 burner-buildings, one bolting and packing house, one power house, a meter house and a warehouse. Only one office is required, irrespective of the number of units constituting the plant. Each unit usually has a capacity of 3,000 to 5,000 pounds of carbon-black per day and it operates every day in the year, Sundays and holidays included. A general lay-out plan of one of these units is shown in Fig. 2.

The power required to operate each unit is 20 to 30 horsepower, which is supplied by a gas engine of the two-cycle type, or where high pressure gas is available, by an ordinary steam engine, the gas being used expansively in the place of steam and being exhausted into the low-pressure gas lines feeding the plant. The practice of thus using gas for power purposes is to be commended because of the saving in cost made thereby, the only expenses being that of the lubricating oil for the piston and bearings of the engine. Where the gas used in operating the steam engine is under sufficient pressure to cause it to frost the cylinder and freeze up the exhaust on expanding, it is warmed before going to the engine by running it through a coil of pipe laid in the burner-building nearest the power house, thus eliminating all trouble from that source.

(To be continued)

CANADA'S SUPPLY OF CARBON-BLACK

Statistics just issued by the Department of the Interior of the United States show that for the year 1922 there was produced in that country 67,795,129 pounds of carbon black from 53,629,214,000 cubic feet of natural gas, an average of 1.3 pounds per thousand. The actual sales of carbon-black during the same period were over 15,000,000 pounds more than the total production, the excess being supplied from stocks that had accumulated during previous years and were held in storage. The increased demand for carbon-black from the rubber industry and the resultant absorption of stocks in storage resulted in a rise in price to 24 cents per pound.

Carbon-black is not yet being manufactured in Canada, but negotiations are now in progress to establish factories in the Alberta gas fields that are remote from centres of population. In 1922 there was exported from the United States to Canada over 1,500,000 pounds of carbon-black, some of which was valued at 40 cents per pound, this grade being used in the manufacture of special printing inks used for embossing, lithographing and half-tone work.

GERMANS MAKE COKE FROM LIGNITE

At a meeting of the Lignite Institute of Freiberg, in Saxony, held recently, a complete economic unit of a trial plant for the manufacture of coke from brown coal or lignites was demonstrated. The coke produced is quite different from that made by the usual coking processes, is very porous, and contains a large quantity of gas. It is described as a brown-coal flame coke. One German firm had an oven of this type, constructed in accordance with the Limberg patents, in operation for about a year, and raw brown coal is treated satisfactorily, even if it contains a high proportion of water-soluble ash. In this process the coal is subjected to the action of inert gases at a specific temperature, and, owing to the careful heat treatment, the yield of tar is stated to be larger than that obtained in other processes.

LARGE DEPOSITS OF COBALT ORE

There is under development in the Cloncurry district of North Queensland, Australia, an important deposit of cobalt ore. Concentrates are being turned out at the rate of 100 tons a day. It will be interesting to see whether this mine, worked for cobalt alone, can withstand the competition of ore from Cobalt, Ontario, where cobalt ore is merely a by-product of silver mining, with arsenic as an additional important by-product.

Letters From Readers

Quebec Asbestos Industry

To the Editor
Canadian Mining Journal

In your issue of Sept. 7th., you published a letter from Mr. Samuel Davis, in which he takes exception to sundry points in my articles of recent date on the Quebec Asbestos Industry, to which I herewith reply.

Mr. Davis apparently agrees with me on the importance of mill fibre production, inasmuch as he informs us of the sales of mill fibre having exceeded the sales of crude for over 20 years. He also tells us that "the same rock from which crude alone was extracted was milled to recover fibre, and it was only milled to the point where it was possible to pay for the cost of milling by the increased value of extracted fibre." This is very interesting and is exactly what the writer advocated.

Mr. Davis then informs us that "market conditions govern the percentage of recovery of fibre in any mill." Surely this is a dream. The productivity of any mill is governed by two things only: (1) the fibre content of the rock going into the mill; and (2) the efficiency of the milling process. Neither of these has any connection whatever with market conditions. Mr. Davis possibly advocates a policy of waste, in order that present market conditions may be maintained, although this seems unbelievable. For it must be allowed that to permit fibre to get away is equivalent to waste; and even the maintaining of present market conditions has already become somewhat difficult, due to supplies of fibre available from South Africa, and other sources, and ultimately will become still more difficult.

The "dust" which Mr. Davis claims "costs more to produce than it will fetch," a sample of which the writer secured twelve hours after a snow-fall last winter about fifty feet from a mill, contained 40 per cent of fibre, most of which was about 1-4 in. long, and some of it longer. I have never suggested that it is either desirable or profitable to make dust, but I do suggest, and most emphatically maintain, that the fibre that has been extracted should be prevented from going to waste, as is now the case in some mills, and therefore I have suggested certain means to attain this end.

Mr. Davis agrees that I am probably correct in assuming that from 25 per cent to 30 per cent of the possible extraction is wasted. I accept his view that 100 per cent of the mill rock yields 75 per cent of its fibre content, but I go further and credit the mills with liberating 87 1-2 per cent of the fibre. The 12 1-2 per cent additional fibre is lost,— *extracted and then lost — allowed to vanish into space with the dust.* As mentioned above, this is and has been the writer's point throughout. Stop the loss of fibre that has been already extracted; do not extract anything that cannot be sold profitably.

According to Mr. Davis, milling methods have not changed appreciably during the last twenty years. It would seem to be true, for the writer knows of one mill being built which is an exact replica in both construction and equipment of one completed in 1913. As probably there is more truth than poetry in Mr. Davis' letter, in view of his long connection with the industry, his admission of lack of improvements in milling procedure during so lengthy a period hardly reflects the progressive spirit which he would have us believe exists.

Maybe the maintaining of market conditions has barred the way to progress and so has brought about the stagnation indicated. An efficient mill will meet all market demands, whether today's or tomorrow's; but the fibre wasted will certainly not pay dividends at any time.

Mr. Davis is apparently not aware that there are a number of mills in the province where only one stage of crushing is the practise, and others with only two stages.

I thank Mr. Davis for the light his letter sheds upon the shady spots, which in some measure probably accounts for the silence the industry has maintained during its struggles to regulate prices, in preference to improving the efficiency of its milling operations.

Montreal, Que. G. Ernest Booker.

THE KEELEY MINE

By ALEXANDER GRAY

A detailed and authoritative description of the Keeley Mine cannot but add to the interest in the South Lorrain silver area. Nothing of the sort has appeared in the Canadian press. London, however, has been favored with the facts, widths and values being set forth as follows:

"The company owns two claims, which adjoin, known as the Keeley and the Beaver Lake. In 1922 the company produced 775,349 oz. of silver, and for the first half of the present year 826,814 oz. The ore bodies are lenticular, the lenses being considerably shorter than those found at Cobalt, but there appears to be a disposition at depth for increase in length and richness, for so far the best ore located has been in the 7th level, 480 ft. below the collar of the No. 3 shaft. There are two working shafts—No. 4 on the Beaver Lake, and No. 3 on the Keeley; the former finishes at the third level, and the other continues down to below the 7th level—at present the deepest working area of the mine. The principal vein —the Wood's—outcrops, about two-thirds showing on the Beaver Lake and the remainder passing into the Keeley claim. No. 4 shaft was sunk on this vein, and is therefore an incline, the vein dipping eastward about 65 deg. The first level at 75 ft. was driven by the original owners, who took out of the property silver to the value of about $6,000. The next level located in the northern section a rich chute known as 'D3,' some 60 to 70 ft. long, of high-grade ore. The first two levels from the No. 3 shaft are of no great importance. On the third level, at 235 ft. from collar, the Wood's vein has been drifted on for 1,200 ft. In the southern section there is a stope 175 ft. long and 75 ft. high in the oxidised portion of the vein. The ore is, however, difficult to treat with the present process. On the fourth level values up to the present have been low. On the 5th level there are three veins of good value. On the 6th level there are also three veins, all of which appear to show high values, which lack of space prevents detailing. On the 7th level there are four productive veins, there being, moreover, two shoots in the Wood's vein. In the Wood's vein 40 ft. assayed from 500 to 14,800 oz. of silver to the ton, one part of the shoot 12 ft. in length, with a width of from 6 to 15 in., assayed 8,000 to 14,800 oz. of silver to the ton. At the south part of the vein a shoot having a length of 198 ft. gave an average assay of 370 oz. over an average width of 19 in. Another vein, No. 26, sometimes called the 'Birthday,' was discovered in December of last year. In this vein has been determined the most consistent shoot of high-grade ore so far located. It had a length of 74 ft., and averaged 2,600 oz. across an average width of 15 in. It is reported that the company, in drifting along the shoot, mined 250,000 oz. of silver without any stoping. This vein is in the south part of the level, and is a branch of Wood's vein, and after very gradually leaving it, parallels it for about 60 ft., at a distance of 2 to 5 ft. It then turns to the north-west, just about the point where the ore shoots begin to develop. At one point it had a width of about 5 ft. Another vein, the No. 20, was discovered in the early part of the year, also in the southern part, containing high-grade ore. The remaining vein, No

16, is a branch of Wood's vein, and has been followed westward for some 226 ft."

It is explained on behalf of the Hamilton-Ehrlich interests, who own a large share of the Keeley capital, that "it is too early for any definite opinion to be expressed as to persistence at depth, but it is very encouraging that the best values are found at the lowest level. The outlook for the mine appears to possess great possibilities."

The latter sentence is commendably conservative and merits emphasis. Keeley management has the distinction of refraining from overestimates where the developments have been so satisfactory. "Well enough" is "good enough." From year to year Nipissing set an example by putting its silver in reserves at about the rate of its output. The Keeley does not require projections into the future since Dr. Bell proved himself to be a prophet in his day and generation—and in his own country—which does not often happen to Canadian mining field-marshals.

BLANKET CONCENTRATION ON THE RAND 19 YEARS AGO

The July issue of the *Journal of the Chemical Metallurgical and Mining Society of South Africa* contains a discussion on blanket concentration by J. M. Neill, of which the following is part:

The tendency now is to substitute corduroy for copper, or where it is not desired to go as far as that, then to make corduroy tables supplementary to copper tables. The case of the old Jumpers mill forms a basis for the latter method, and points of interest applicable to the present discussion [on blanket concentration] may emerge from a short history of what took place there.

In October, 1904, my attention was drawn to the large quantity of so-called free gold in the tailing. This gold did not float on the pulp, but it did float on mercury, and would not amalgamate. I concluded the gold was coated, and made the following experiment:

One of the 11 ft. x 5 ft. copper plates was covered with navy canvas, the pulp run over it for some hours, then stopped. Assays of each foot of concentrate were made and the tailing examined. It was found that over 90 per cent. of the recoverable gold was caught on the first 18 in. of canvas, and the tail exhibited apparently no free gold.

Small blanket tables were then placed at the foot of the copper plates. Those were all in position by the end of the month and were 5 ft. long by 5 ft. wide. Each blanket table was divided into three compartments by two strips of wood running lengthwise from top to bottom. The pulp was fed through holes in the top launder, leading to each compartment. The blankets could be cleaned by plugging the holes, rolling up the canvas, burlap or black blanket as the case might be, washing and returning it, and proceeding to the next compartment. The idea in this case was to avoid stopping the stamps. A barrel was put into use and much the same results got as described elsewhere.

In the meantime cyanide tests were made on the supposed free gold, varying strengths of cyanide, alkali and time of treatment were tried, but practically no gold was brought into solution.

The gold was found to be coated with clear and glasslike ferrous silicate, which could be distinctly seen through the microscope. The net result of the new arrangement was that the mill, which had been getting under 50 per cent. of the total recovered gold, sands alone being at that time cyanided, very quickly obtained a recovery of over 60 per cent. of the total when sands and slimes were being treated.

The burlap jute or black blanketing required cleaning twice each eight hours' shift. I tried a number of materials for the purpose of concentration and found that some collected more concentrate than others, with a decrease in value for the increase in bulk, but that the tail remained fairly constant. Milling was through 60 screening. There were no tube mills in use.

The next step to which I would draw attention was an increase in the total recovery, which rose to 70 to 72 per cent. recovered in the mill. This was brought about by defloating the lustrous minerals, as already described in the *Journal* of this Society. To be added to that description is the additional fact that mercury losses, which were based on mercury used in feeding and dressing, as was the system in those days, were reduced from 20 to 21 per cent. to between 6 and 8 per cent.

The rippling motion mentioned will have no effect in causing floating particles to sink, but by the eddying resistance set up it may cause floating particles to take longer to rise to the surface, and also particles with a tendency to sink may be caused to take so long to do so that they are carried completely beyond the recovery point. Therefore corduroy with less than 3-16ths of an inch corrugation might be tried across different portions of the table and either chemical or mechanical means of deflotation to obtain better extraction, especially in the area of the fourth and fifth blankets.

Regarding mercury substitute, I tried grease at the Geduld, the resulting recovery being within a few per cent. of that recovered by mercury. The mercury position having eased, this line of investigation was not pursued further, although it has distinct possibilities.

EFFICIENCIES OF CYANIDE SOLUTION

An investigation of the comparative solvent powers of potassium cyanide, sodium cyanide, and calcium cyanide has been undertaken at the Rare and Precious Metals Station of the United States Bureau of Mines, Reno, Nevada. It would appear from preliminary results that there is not much difference in the three salts, although the cyanide loss with the calcium salt seemed to be greater than with the other two. Mill tests on a number of ores that are typical of certain sections were made to determine whether these were amenable to cyanidation, and the results were reported to the operators.

HOW IT HAPPENED

A lumberjack with a broken leg was taken to a hospital for treatment. After the leg had been set, the nurse asked him how the accident occurred. He replied:

"You see Ma'am, it was this way: I was skyhooking for the Potlach Lumber Company and I had only one ground mile. He sent up a big blue butt that was a heavy one. I saw her yaw and yelled to him to give her a St. Croix, instead of which he threw a sag and gunned her, and that broke my leg."

"Yes," the nurse replied, "but I don't exactly understand."

"Neither do I," said the lumberjack. "That darn fool must have been crazy."

Mining and Prospecting in Central Africa

Copper, Radium, Tin and Cobalt, Produced in Katanga. Gold, Copper, Asbestos and Graphite Concessions in Sudan

One of the largest unexplored mineral areas of the world lies in central Africa. The phenomenal rise of the Katanga region of the Belgian Congo as a producer of copper, radium and other metals during recent years has been due in no small measure to the foresight and energy of Mr. Robert Williams, who is one of the conquering army of bankers, merchants and business executives that have marched out of Aberdeen, Scotland, to all quarters of the globe. Mr. Williams was formerly very active in organizing and directing gold mining operators on the Rand. Then he joined forces with Belgian capitalists to open up the Katanga deposits. Now he has undertaken to explore a region on the northern side of the equator in the little known upper Sudan, round the continental divide between the Congo and the Nile. In speaking recently in London to shareholders of the British companies whose capital is invested in the undertakings, Mr. Williams said, in part, as reported in a recent issue of the *South Africa Mining and Engineering Journal.*

Vast Belt of Copper Ore

In 1902 I said I believed the Katanga copper belt would ultimately produce 1,000 tons of copper per day, if everything that makes for economical working were brought to bear, particularly cheap transport to the coast and Europe. Since I have visited the copper belt this time I am more than ever confirmed in this opinion. I had long formed the opinion that the so-called mines discovered over 250 miles of Katanga had probably originally been glaring green carbonate outcrops which had attracted the natives, who had probably found enough ore without bothering to explore for extensions underground, and that in all probability what we had discovered was one continuous reef which would be found as rich underground, where it had no outcrop, as where the natives had worked it. I advised George Grey and every engineer we sent to Katanga to prospect on those lines. This view was confirmed by Mr. Farrell, the first American mining engineer I sent out to report on these deposits, and it was further confirmed by the discovery of ore at Kambove adits, and the discovery last year at Ruashi mine of 5,000,000 tons of ore containing 500,000 tons of copper, 1,500,000 tons of which is direct smelting 19.3 per cent. ore. Further drilling is proving ore all the way between Ruashi and the Star, and beyond the Star, and all where nothing outcropped. At Luushia the extension of that mine has been proved for miles on either side. But what shows the continuity of this great copper belt most of all is the western section of it, which I had never seen before. I travelled over 120 miles of it. Unlike the eastern section, where the wealth is mostly under surface level, that of the western section is chiefly above surface level. It stands up in bold hills, the geological formation of which is the same as the eastern section, with the same ore, with slight variations as to value. You can stand at Ruwe mine, as I did, and see these bare hills of copper standing out of a sea of forest country, marking the line of the great copper reef, with faults here and there, right away to Fungurume. I motored along the Fungurume mine and its extension for about 20 miles. The highest point of this range is 1,000 feet above the local river level.

Enormous Copper Reserves

I went over most of these hills of copper accompanied by Mr. Barzin, the mining engineer of the Union Minière, who knew them all, and each and every one had been proved by tunnels, surface trenches and drills. In one mile of the 20 miles at Fungurume, 9,000,000 tons of ore had been proved. At Musonoi there is a group of mines within 1,100 miles by rail of Lobito Bay, in which millions of tons of ore have already been proved to exist. At Ruwe Mine, in this group, £100,000 in gold has already been extracted. Gold, platinum, palladium, vanadium and copper exist there. The existence of large supplies of cobalt and uranium ores has also been proved in the eastern section. About ten miles out of the 250 miles of this copper belt has given a development of 68,000,000 tons of ore, containing about 4,500,000 tons of metallic copper. These ten miles represent operating mines and proved bodies of ore over the whole 250 miles. If ten miles has given 4,500,000 tons of metal, 40,000,000 tons of copper is a very conservative estimate for the whole 250 miles. I believe that the real policy for the Union Minière to pursue is to go ahead with all processes and try to perfect them all as they proceed.

Radium, Tin and Cobalt Ores

I also visited the uranium deposit at Chinkolowe, and the development work done there has already proved the existence of a sufficient quantity of rich ore to supply the radium works at Oolen for a long period. Since January, 1923, the plant has been producing radium commercially on a scale sufficient to cover amply the requirements of the whole world. This new industry is now well established, and is running under very satisfactory conditions, entirely in conformity with our expectations.

The production of cassiterite during 1922 amounted to 670 tons, and during the first five months of 1923 it amounted to 302 tons. It is intended to increase the monthly output to about 80 tons in the near future. This cassiterite is of high grade, and frequently reaches 72 to 74 per cent. tin, and the resulting metal is of very high quality. A new tin factory is now in operation at Hoboken for the treatment of the Katanga ores.

As a result of tests on the cobalt alloys made at the Lubumbashi smelters last year, an electric furnace is now under construction in Katanga for the production of high-grade cobalt alloy. This alloy will be exported to Belgium, and a treatment plant for this material will be installed at the Oolen works.

The Luena collieries in Katanga, which I also visited have reached the stage of regular production, the output for 1922 being about 60,000 tons of coal, and there is reason to hope that this will be doubled during 1923

Large-Scale Prospecting in Upper Sudan

While in Khartoum I discussed the affairs of the Nile-Congo Divide Syndicate with the authorities there, and am pleased to say I have been able to settle in principle with the Sudan Government a satisfactory basis for the further development of our interests. The general lines of the arrangement which the Sudan Government is prepared to accept are: First, that the syndicate will have five years' exclusive prospecting rights over 60,000 square miles on condition that it spends £100,000 during that period. Second, that the syndicate would have the right, subject to reasonable conditions, to work any payable discoveries it may make either in partnership with the Government or on a basis of a reasonable mining lease and royalty. The details are now being discussed, and certain conditions will have to be compiled with, but I can say that

the Sudan Government authorities are dealing witih me in a fair and broad-minded way.

Gold, Copper, Asbestos and Graphite

During the past year prospecting work has been carried on in various parts of the concession, and up to the present twenty-six prospecting areas, each of ten square miles, have been registered. Of these areas thirteen are for alluvial gold, eight are for copper and gold ore deposits, three are for reef gold, one is for asbestos, and one for graphite. The work done has been confined to prospecting, and has resulted in the discovery of further extension of the gold-bearing copper reefs in the north-western part of the concession, and according to Mr. A. P. Thomson, who is in charge of the work in that part of the concession, the copper occurrences, apart from the large Hofrat-el-Nahas mine, extend over a distance of thirty-six miles. Two areas located along a twenty miles extent of the Ibba River for alluvial gold have recently been examined by our engineer, Mr. J. G. Bower, who reports favourably upon them. In the south-eastern part of the concession prospecting work has resulted in showing a very general distribution of alluvial gold in a large number of main and tributary waterways over a large area, which show very encouraging indications in a number of localities. On the whole the results of the work done to date are very encouraging.

PERSONAL AND GENERAL

Mr. C. H. Poirier, of New York, has been visiting the Porcupine and Cobalt districts recently.

Mr. Leslie Steindler has returned to New York from Northern Ontario, where he visited the properties of the Dominion Reduction Company, Lorrain Consolidated and Croesus.

Mr. H. A. Barker, of London, who has been visiting Northern Ontario, has sailed for Buenos Aires.

Dr. Charles Camsell returned to London last week after inspecting the oil-fields of northern France and Belgium.

Mr. James J. Denny, metallurgist of Nipissing Mines, is in Bermuda on a holiday.

Mr. R. M. Wolvin visited the Scotia steel plant at Sydney Mines when on his tour of inspection recently in Cape Breton. The plant has been closed down for some time, but Mr. Wolvin said emphatically it would not be scrapped.

Mr. H. J. McCann, assistant manager of the Dominion Coal Company, has taken over the duties in Sydney relinquished by Mr. D. H. McDougall. He has been the temporary incumbent of this position on former occasions.

Mr. T. J. Brown, Deputy Minister of Mines for Nova Scotia, visited recently the property of the Eastern Harbour Coal Mining Company, where it is hoped sufficient coal will be disclosed by development in progress to warrant establishing a colliery.

Messrs. J. B. Petrie, Mechanical and Electrical Engineer, and Angus McDonald, Superintendent of Mines, Wabana, spent a few days in Cape Breton lately, where their many friends were pleased to meet them.

DIAMOND PRODUCTION

The value of diamonds produced in South Africa, during the six months ended June 30 is placed at more than £2,000,000, or double the total for the whole of last year. It is reported that certain European interests are endeavoring to establish a diamond-cutting industry at Kimberley. Definite steps have been taken to obtain concessions as well as the support of the Union Government.

RADIO INSTALLATIONS IN THE NORTH

The Canadian Corps of Signals are to erect wireless stations for the North West Territories and Yukon Branch of the Department of the Interior and a party is now in the Yukon territory engaged in installing the equipment at the Dawson and Mayo stations before the winter sets in. Early next spring another party will go to McMurray, northern Alberta and Simpson in the North West Territories and install radio apparatus there. Upon the completion of the stations, competent operators will be placed in charge and it is anticipated that this system will do much to assist in the development of these districts.

For many years the Yukon territory has had to depend on the telegraph line from Dawson to Hazelton, B.C., for communication with the outside world. This line was maintained at a cost of more than a quarter of a million dollars annually and notwithstanding the untiring attention to duty of the patrols, especially in the great wilderness between Hazelton, B.C., and Whitehorse on the Yukon river, interruptions occurred in the service, resulting in losses to those engaged in development work in the territories. One of the heaviest snowfalls on the continent occurs on the eastern slope of the Rocky Mountains in the district traversed by the telegraph line, so that in the past the line patrols have had to contend with deep snows in winter and floods and forest fires in summer. Incidentally the new service will bring means of communication to the districts in which development has made rapid strides during recent years, namely, the oil and gas fields of northern Alberta and the Mackenzie district, and the gold and silver areas of the Yukon.

Will Replace Wire Lines

When the proposed four wireless stations have been completed and are working, direct service by wire between Dawson and Hazelton will be discontinued. However, for the use and benefit of transportation companies operating boats on the Yukon river and for the residents of Whitehorse in the Yukon and of Atlin, B.C., the service will be continued between Dawson and Atlin. All telegraphic communications between the Yukon and the outer world will then be transmitted by way of Mayo, Simpson and McMurray. At the last named point connection will be made with the Government telegraph wire line to Edmonton. The new system will have a daily capacity of 5,000 words, which, although considered greater than will be required for some time, provides for future expansion. A great saving in annual upkeep of the Yukon service will be effected by the radio service. The cost of installation is estimated not to exceed $75,000 including construction of necessary buildings and cost of aperation for one year. The cost of maintenance will be much below that for the telegraphic service.

The value of radio in the far north is rapidly being recognized. For a number of years officials of the Government and others have been carrying, as part of their equipment, receiving apparatus. To surveyors, receiving sets are absolutely essential in order to secure the time from the Observatory to determine longitude, while travellers to the north in general speak with appreciation of the part being played by the wireless in the development of this great Canadian hinterland. — *Natural Resources.*

The Empire's Resources of the Base Metals

Sir Richard Redmayne Gives Summary of Copper, Lead, Zinc, Tin and Aluminium Resources, and Compares Them with the World Supply

Sir Richard Redmayne, the eminent British authority on the base metals, read a paper recently before the Royal Society of Arts, in which he discussed in a broad way the Empire's resources in these metals and their relation to the world's supply. He said, in part:

Copper

Copper, which figures so largely in the base metal industries, is the metal as to which the British Empire is worst off in point of domestic supplies.

The average annual world's output of copper at the beginning of the Nineteenth Century was only about 9,000 tons; by the middle of the century it had grown to 40,000 tons, and at the end of the century to over half-a-million tons. In 1913 it was nearly one million tons, and in the record year of 1917 it had amounted to one and one-half million tons.

In the year 1919, the British Empire contributed only 6 per cent. to the world's output of copper; in 1920 7 1-2 per cent., and in 1921 8 1-2 per cent.

The country chiefly affected by the decline in production since 1917 is, of course, the United States of America, for she produces normally over 50 per cent. of the total world's output, and large as is her proportion of the world's production, she controls a still larger production by ownership of mines in other countries, notably Chile and Peru.

The British Empire, with Canada and Australia as the chief producers, does not supply sufficient copper for her needs, nor even for the needs of the United Kingdom alone. Thus, the pre-war consumption (1913) of the three greatest copper consumers in the world was as follows:—

U. S. A.	340,000
Germany	225,000
Great Britain	138,000

or, in the case of Great Britain, one and a half times the Empire's output.

The great increase in the world's production and consumption of copper is chiefly due to the vast expansion in the use of electricity for power and lighting purposes which has characterised the last 25 years. Indeed, the importance of the metal in modern industry is shown by the fact that the motor car trade in the United States alone consumed 50,000 tons of copper in 1922.

From the point of view of potential resources, the British Empire contains extensive areas of copper-bearing ground which might, with advantage, be subjected to close investigation with a view to increasing the output of that metal.

From this Empire point of view Canada presents the most likely source of increased supply, particularly British Columbia. It is reported that millions of tons of copper ore have been proved in Northern Manitoba, where development has been active for several years.

The production from the Otavi mines in South West Africa is also increasing, and production may soon be expected on a larger scale from Papua, where there are extensive deposits of high grade ore.

The deposits of the Union Miniére du Haut Katanga in the Belgian Congo are largely controlled by British capital. Hitherto the production from these mines has been hampered by length and cost of transport, but these difficulties are gradually being overcome and the production, which in 1921 was about 30,000 tons, is increasing rapidly, being over 40,000 tons in 1922.

The chief hope for the more economic treatment, and consequently gradual lowering of the price of the metal, would appear to be in the wider application of flotation methods in concentration of the ore and new leaching processes for the extraction of the metal from the ore, permitting as they do large deposits of low grade ore to be worked.

Lead

The world's production of lead ore, expressed in terms of metal (long tons) for the year 1913 was 1,705,000 tons and for 1921 had declined temporarily.

The British Empire is in a somewhat better position in respect of lead than as regards copper. Taking the years 1919, 1920 and 1921, the Empire produced respectively, 17 1-2, 12 1-2 and 24 per cent of the world's production. The United States, Spain and Mexico are the greatest producers in the world.

But the amount produced within the Empire falls short of the amount imported into the United Kingdom. There is imported annually into the United Kingdom something over 200,000 tons of lead in one form or another, but she exports a certain proportion of this, either as pig lead or manufactures of lead, to the extent of between 70,000 and 80,000 tons.

Before the War, Germany used to obtain from her own mines about 50 per cent. of the lead smelted in that country: the balance she drew from Australia and Mexico—largely from Australia in the form of concentrates, but the increase in smelting capacity in Australia during the War must materially affect the present position in this and other respects.

From all one can learn it would appear that the lead mining industry is exceptional in being one of the few branches of the base-metal mining industries which is not over-developed. It is remarkable also, that no great discoveries of lead ore have been made within recent years, and it looks as if the developed resources were being exploited near to, if not up to, their full capacity. Although we are far from meeting our requirements in lead, the Port Pirie lead smelting works of the Broken Hill Associated Smelters Proprietary Limited, in Australia, (the largest works of the kind in the world) is capable, when working to full capacity, of producing 200,000 tons of pig lead and 8 to 12 million ounces of silver per annum.

The United States is the largest producer of lead in the world. It is also the greatest consumer of that metal. Spain and Australia both export more lead than America.

Taking the last pre-war year, we find that 82 per cent of the world's production was derived from five countries, viz., the United States of America, which accounted for 37 per cent; Australia, 20 per cent; Spain 15 per cent.; Germany, 6 per cent.; and Mexico, 5 per cent.

Lead enters into a vast number of industries. It is, however, chiefly consumed in the making of white-lead paint, pipes and sheets, coverings of cables, and as an alloy with antimony and tin. It is also used largely for storage batteries, in enamel, glass, pottery, etc.

Britain is the largest importer of lead in the world.

Before the War, Spain supplied 38 per cent of our requirements; Australia 28 per cent.; U. S. A. 15 per cent.; and Mexico 10 per cent.

The perfecting of the flotation process of concentration has had the effect of rendering possible the retreatment of considerable accumulations of zinc-and-lead-bearing tailings and residues at the Broken Hill Mines of New South Wales.

Before the War, a total loss of 5 per cent. in smelting lead concentrate was considered good practice with a fairly good equipment. Of course, in smelting low-grade concentrates or slags containing lead, which had to be resorted to during the War, particularly on the Continent, the losses were much greater. The loss in smelting Serbian slag containing 8.5 per cent. lead was as high as 24 per cent. I merely mention these facts as pointing to the scope still remaining for research work.

Our resources of lead, within the Empire, are considerable. Burma alone should contribute greatly in future to the British requirements in this respect, and, looking to potentialities at home, I am one of those who believe that our own supplies will be found to be well worth further exploitation as foreign costs increase. It was the more cheaply worked deposits of Spain which originally rendered unprofitable the lead-mining industry at home, but since the day when lead-mining was extensively prosecuted in this country, methods of extraction have greatly improved.

Industry is very active in the United States of America, and credible observers consider that during the present year that country will consume more lead than it produces.

Galena—lead ore—is the chief source of silver, and the position of the precious metal in point of demand, and consequently of price, must have an important bearing on the value of lead.

Zinc

The ores of zinc are closely associated with those of lead, and the two metals are in many cases obtained from the same mine. Just as in the case of lead, the United States of America far exceeds any other country in the quantity of zinc she produces.

Taking the years 1919, 1920, 1921, the contribution of the British Empire to the zinc production of the world was 1 per cent., 6 per cent., and 30 per cent. respectively, of the world's production, the low figure for 1920 being due primarily to the strike at the Broken Hill Mines in Australia.

In point of consumption, taking the year 1913 as a normal year, the position stood thus:

United States absorbed	308,000 tons.
Germany	228,000 tons.
United Kingdom	191,000 tons.

Those three countries are the chief consumers of the metal. The British Empire meets only one-third of the requirements of the Mother Country.

The use of zinc in commerce has grown rapidly. Formerly its use was practically restricted to the manufacture of alloys with copper, tin, and lead, but the realisation of its value as a coating material and the discovery of the galvanising process gave an enormous impetus to the consumption of zinc, and probably 65 per cent. of the total zinc smelted is consumed in this way. But there are numerous other uses to which it is put, one of the most recent being in the form of an alloy with aluminium in the manufacture of aeroplane parts and shell fuses.

The two most noticeable features in respect of zinc at the present time are:—

(1) The rising production of electrolytic zinc, notably in Tasmania, Canada and the United States of America, and

(2) The fact that, as a result of the War, the world's smelting capacity of zinc is largely in excess of the ore-production. The capacity in this respect of the United States of America alone is now 800,000 tons per annum.

As Mr. Gilbert Rigg has informed us in his interesting article, "The Zinc Industry at the close of 1919," prior to the War, there was, for all practical purposes, but one method of extracting zinc from its ores, namely, the distillation process. "The possibilities," he said, "of leaching and electrolysis had been discussed and tried out for more than a quarter of a century, but, in spite of numerous attempts ranging in scale from laboratory experiments to more ambitious efforts reaching in at least one case to very large expenditure indeed, the effect upon the industry was so small as to be negligible."

The electrolytic process is now an acknowledged commercial success, although still the greater part of the production is due to distillation.

As illustrating the headway made by the electrolytic process of recovery one may point to the potential production of electrolytic zinc from the following well-known concerns:—

Anaconda Copper Mining Co., Great Falls, Montana, 55,000 to 60,000 tons. (This company recently acquired the American Brass Company, and will require more than this quantity of zinc for its own consumption).

Electrolytic Zinc Co., Risdon, Tasmania, 40,000 to 60,000 tons.

Consolidated Mining and Smelting Co., Trail, B. C., 20,000 to 25,000 tons.

Judge Mining and Smelting Co., Park City, Utah, 2,500 tons.

Brunner Mond and Co., England, 1,700 tons.

It would certainly seem as if electrolytic extraction will gradually supersede the distillation process with resultant saving in cost.

Black, indeed, was the outlook for zinc two years ago; there was little market and nearly all the home smelting-plants were shut down. By the end of 1922 the position had materially improved. In America, for instance, the metal had nearly doubled in price, and there were barely two weeks' supplies in stock, thousands of tons having gone to Europe to meet the increased demand. In 1921, the production was less than half that of what may be described as a "normal" year (e. g., 1913). Zinc with copper constitutes the alloy we know as brass. Improvement in the engineering trades means an increase in the demand for zinc. Production in the present year is not likely to exceed consumption, stocks have greatly diminished, and the engineering trades are slowly improving. A recovery from the last two and a half years' depression would appear to be in sight.

Tin

The Empire position in respect of tin is different from that of the three previously named metals, inasmuch as the Empire is the chief contributor to the world's production, accounting for more than half of the annual output. The Malay States are the chief producer, contributing over 36 per cent. of the world's output; then follow Bolivia and the Dutch East Indies, with about 20 and 15 per cent. respectively.

At present the consumption and production of tin appear about to balance, a feature which may be contrasted with copper where during the last two or three years drastic curtailment of output was resorted to.

Tin is peculiar in that its sources are few and far between, and few new deposits have been discovered in recent years, although it appears probable that the Belgian Congo will become an important producer in the not far distant future. It would seem that, unless really extensive deposits are yet remaining to be discovered, tin will be one of the first of the base metals to be exhausted, and so far as I am aware, no satisfactory, or, at any rate,

cheaper substitute than tin as a covering medium in "tin-plates" has as yet been found, and in the manufacture of tin plates lies the chief consumption of tin. For the purposes of cooking utensils aluminium will probably take the place of tin, copper and brass.

Tin is of importance in the making of certain alloys, e. g., bronze, fusible metal, pewter, Babbitt metal and type metal.

The smelting of tin ore is concentrated in few hands, although the tin smelting capacity of the world is well in excess of the annual supplies of ore. In this respect the Straits Settlements heads the list, with a capacity of about 58,000 tons, Great Britain coming second, with a capacity of about 34,000 tons, and the United States of America third, with a capacity of 30,000 tons. These figures are in terms of metal, the total world smelting capacity being about 175,000 tons per annum.

An interesting feature of the tin situation is that costs have been brought down to a point where the industry will be in a healthy condition as soon as more normal consumption is reached.

Aluminium

Although aluminium, in the form of the silicate, is perhaps the most plentiful metalliferous mineral in the world, owing to difficulty of extraction, it is only of late years that it has come to be used commercially on a large scale. Although, too, during the war period the Central Powers, being short of supplies of bauxite, were forced by pressure of circumstances to endeavour to extract aluminium from clays, this is not yet a normal commercial possibility.

Bauxite, which contains from 30 to 60 per cent . of alumina, is the chief source of the metal, but only the comparatively pure mineral can as yet be used profitably for extraction of the metal.

The uses to which aluminium is put are very numerous, largely owing to its lightness and resistance to oxidation. It forms alloys with several other metals; is used in the construction of aeroplanes and airships, in telegraphy and telephony; in the manufacture of explosives, and many other directions. If a process could be discovered whereby aluminium could be applied to the coating of iron its use would probably be vastly extended.

In 1913 the British Empire accounted for little over 1 per cent. of the world's production of bauxite; in 1917, 2 per cent.; in 1920, 5 per cent, and in 1921, 9 per cent. The increase in the contribution from the British Empire is due to the development of the deposits in British Guiana

The United States of America is the chief producer of bauxite, contributing 43 per cent. (1921) of the world's output.

France comes next with 25 per cent. (1921).

A deposit of high-grade bauxite is not a commercial proposition unless the minerals can be mined and shipped at cheap rates to the smelting locality. For the actual production of the metal water-power is desirable and is usually employed. Thus, though bauxite is not mined in Canada, the cheap water-power available at Shawinigan Falls, Quebec, makes it profitable to extract aluminium from imported ore.

Besides the deposits of British Guiana there exist rich deposits of bauxite in India and the Gold Coast.

"CHEAP" LABOUR IN INDIA

Even "cheap" "labour" has disadvantages. The case of India is cited in the current issue of *The Mining Magazine*. In the Bengal field the miner, who remains essentially an agriculturist, attends to his crop ahead of his mining duties, and consequently during the harvest it is almost impossible to man the mines. Marriage festivities likewise interfere. The past season has been an auspicious one in many parts of the coalfields. The season commenced in March and the celebrations continued until June. In one village twenty-two marriages occupied the inhabitants for six weeks, and during that time not one miner was at work. Though wages are high, prosperity seems to induce idleness and intemperance rather than industry. Attempts to economize labour by the use of coal-cutting machinery have been frustrated by the indolence of the natives engaged in loading away the coal. The net result, it is concluded, is that for at least a generation to come the coal resources of India will not be made available on a basis that will make that country a serious industrial rival of Great Britain.

INDUSTRIAL ITEMS

The Canadian Ingersoll-Rand Company has issued a new 36-page bulletin, K-201-B, describing Leyner Drill Sharpeners. The construction and operation of both the standard size and the smaller "Jacksteel" sharpener are described. Many useful hints for making good bits are included. The bulletin can be had by those interested on request.

The Bristol Company, Waterbury, Conn., U. S. A. manufacturers of recording instruments, whose Canadian distributers for the Eastern territory are Powerlite Devices Limited, Toronto and Montreal, and Gorman Limited, Edmonton, for the Western territory, have just published a new thirty-two page Bulletin on Bristol Tachometers, Recording and Indicating, which is now ready for distribution. Such instruments are finding a wide use in modern metallurgical works.

The Sullivan Machinery Company has issued recently Bulletin 72-H, describing their drill sharpeners, their construction, and their numerous uses. Bolts, chisels, and numerous other forged products can be made conveniently by these machines in addition to rock drill bits. Class "A" sharpeners are massive and durable in design and construction and have a large capacity and a wide range of usefulness. Class "B" are of lighter design and are meant particularly for hammer drill bits and shanks.

The Link-Belt Company, Chicago, has purchased the Meese & Gottfried Co. of San Francisco, Los Angeles, Seattle and Portland, whose line of production is similar to its own. A new organization known as Link-Belt Meese and Gottfried Co., with headquarters at San Francisco, has been formed to handle the Western business of the combined companies. By this means a better service will be offered to the customers of both organizations, which have always had the best reputation for quality and service.

GYPSUM MINING RESUMED

The International Gypsum Corporation has resumed operations at the Bellemarche quarry in Inverness county, Cape Breton. The quarry is 3 1-2 miles distant by railway from the shipping pier at Eastern Harbour. There are several beds available, and the ore being worked has a face 70 feet high, composed of gypsum of very good grade. The property is equipped with a mill for calcining the raw gypsum as required. The chief market is in the United States. Formerly a large part of the company's product was shipped to St Lawrence ports.

Oil Refining

The Frasch process of refining crude sulphur-bearing Canadian and Ohio oils has increased their value seven-fold.

THE MINING DISTRICTS

By THE JOURNAL'S CORRESPONDENTS

NORTHERN ONTARIO

Larder. — The Crown Reserve has started crosscutting on the 425-foot level of its Larder Lake property, and the vein should be encountered in the near future. Drifting done to date on the 550-foot level has given satisfactory results. It is understood that good ore has also been encountered in diamond-drilling at a depth of 500 feet in the company's North Crown property in Porcupine.

On the Associated Goldfields Larder Lake property, which adjoins that of the Crown Reserve, a total of 950 foot of drifting has been done on the 500-foot level, with values that are understood to be very satisfactory. A crosscut has been run to intercept the vein on the 750-foot level and the shaft is being continued to 1,000 feet.

Kirkland. — The Harvey-Kirkland is continuing work on the 200-foot level. A new hoist has been ordered and when this is installed the shaft will be continued to 400 feet.

South Lorrain. — The South Lorrain area continues to attract a good deal of attention, but outside of the operations under the management of the Keeley and Mining Corporation, very little actual work is being done. Keeley interests have taken over the Maidens property, and are diamond-drilling it, while the Mining Corporation is sinking a shaft on the Lorrain-Trout Lake property. This shaft has reached a depth of 300 feet, and is being sunk on the extension of the Woods vein. Very encouraging values were encountered in the shaft, but no large amount of high-grade ore has yet been found. The Lorrain Consolidated will shortly be in a position to commence underground work on their property, and are reported to be making preparations, but so far little has been done.

Cobalt. — During the month of August shipments of ore and concentrate from Cobalt over the T. & N. O. Railway amounted to 898 tons. Shippers were: Coniagas — 44 tons; Mining Corporation — 645 tons; McKinley-Darragh — 39 tons; O'Brien — 126 tons; and Keeley — 43 tons. During the week ending September 22nd, O'Brien shipped 64 tons, Keeley 43 tons and Mining Corporation 39 tons.

Work on the Victory Silver property has been stopped, owing to shortage of funds.

At the Genessee property, drifting is being done on a promising vein on the 350-foot level. At the annual meeting of the Genessee, Mr. F. L. Steenman was appointed Managing Director and Vice-President.

The Menago property, which is operating the Colonial Mine of Cobalt, has recently encountered more high-grade ore. During the past few weeks values underground have been more consistent and of better grade than were formerly encountered. The company is getting ready to begin shipments of mill ore to the Mining Corporation mill.

Porcupine. — On the Newray property in Porcupine, which is under option to the Coniagas, the shaft is practically completed to the 400-foot level, and when this is finished, further work will be done at 400 feet and the shaft will be continued to 1,000 feet.

Sinking has been started at the West Dome Lake below the 600-foot level, and it is understood that the shaft will be continued to 1,000 feet. Drifting has also been started from the Dome Lake workings with the intention of carrying the workings through to the West Dome.

The new incline shaft of the Davidson has reached a depth of about 100 feet. Progress is not very rapid, in view of all the reports issued regarding the intention of the company to equip and develop it with the least loss of time.

Diamond-drilling has been started on the Porcupine-Grande property, which lies near the Three Nations.

A report has been issued by the directors of the Vipond, which deals in a very encouraging way with the recent developments on the property and with its prospects for the future. The most important development during the year has been the discovery of the No. 10 vein, which has been opened from the surface to the 600-foot level. Development of this vein is giving much higher grade ore than the general average of the mine. Ore reserves as of July 15th were estimated at 210,885 tons, of an average grade of $6.62 a ton, or a total of $1,396,000. Since that date 100,000 tons of $10.00 ore has been developed, and it is understood that since the report was issued ore of a much higher grade has been encountered. The mill is being rebuilt and its capacity increased from 70 tons a day to 150 tons a day, and it is expected that it will be ready for operation by the first of December. The financial position of the company is very satisfactory. At the time the report was issued the company had $200,000 cash on hand and at the present time has between $160,000 and $170,000.

Hollinger Wins Appeal.—The Appellate division of the Ontario court has handed down its decision in the case of the Hollinger Mines against the Northern Canada Power Company, in which the Hollinger asked for $1,800,000 damages for loss suffered from power interruptions during the power shortage of 1921. The decision is in favor of the Hollinger, and reverses the decision of the Trial judge. Sir William Meredith, who was one of the judges of the Appellate Court, has died since the case was heard, so that the judgment was handed down by three judges, of whom two decided in favor of the Hollinger, and one against allowing the appeal. As the Trial judge gave a decision in favor of the Power Company, this makes two judges for and two against. The case will be carried further, and it is understood that instead of going to the Supreme Court in Ottawa, application will be made to carry the matter direct to the Privy Council, and this application for appeal to the Privy Council will probably be heard in November. If the Privy Council should decide in favor of the Hollinger, it is understood that further damages suffered during the power shortages of 1922-23 will be asked for, and as this shortage was much more severe than the one in 1921, the amount would be proportionately larger. If the decision of

the Appellate Court is upheld, this does not necessarily mean that the Hollinger will obtain all the damages asked for, as this question would go before a referee, who would decide the amount. This decision by no means ends the complicated power situation in Northern Ontario, because the Power Company has sued the Hollinger asking that the Hollinger should be compelled to sign a contract for its full power requirements, and a decision in this case is expected shortly. This latter decision is of more vital importance to the Power Company than the one regarding damages for power interruptions, as the Power company has committed itself to the development of 20,000 h.p. on the Quinze River, and this involves the expenditure of several million dollars. If it were finally determined that the Hollinger did not have to take all its power from the Northern Canada Power Company and were allowed to use the power it is developing on the Abitibi River, the Northern Canada would have a surplus of power from its plants on the Metagami River alone, without taking into consideration the amount to be developed on the Quinze. It is, of course, to be expected that this latter action will also be carried through to the Privy Council, so that it will still be a long time before the question is settled. In the meantime, the Hollinger is proceeding with its work on the Abitibi River, but is not making very substantial progress. The situation is further complicated by the fact that the Hollinger has based its plans on a 60-foot head, and this would wipe out the Sault Rapids, to which the Abitibi Pulp and Paper Company has certain rights. The Abitibi Company may be expected to oppose strenuously any infringement of these rights. The Hollinger plans have not yet been approved by the Government.

NORTHWESTERN ONTARIO

Silver Reported East of Nipigon.—A prospective new silver field is being actively prospected in Northwestern Ontario. Within the past few weeks between 700 and 800 acres have been staked and recorded with Mining Recorder J. W. Morgan, Port Arthur, and applications are continuing to come in. The prospecting, staking and recording is being done by men from Cobalt, Timmins, Schumacher, and other points in the Cobalt and Porcupine areas, among them Messrs. Currie and Barrie Johnson.

The new field is located about fifteen miles east of Humboldt Bay on the east shore of Lake Nipigon and the claims so far recorded lie along the southerly branch of the South Branch of the Onaman River. This locality is easily accessible from the Canadian National Railways, Transcontinental line, or by water up the east shore of Lake Nipigon, from Orient Bay, on the main line of the Canadian National Railways.

Very little is known as to the values being encountered, or the width, length or character of the veins; but from the enthusiasm displayed by experienced prospectors, it is believed that something substantial is being showed up, which may prove on development to be another profitable source of silver.

Activity at Foley Mine.—The British Canadian Mining Company, of which Senator George W. Fowler, Ottawa, is President, are displaying considerable activity at the old Foley Mine, near Mine Centre. The buildings have been repaired and several new ones erected. Pipe lines are being laid preparatory to unwatering the South shaft, that was put down 420 feet in former operations. The Foley is located in a promising geological section, of somewhat limited extent, with numerous veins carrying encouraging surface values that warrant intelligent prospecting and development. At present there are a number of prospectors at work in this area, carrying on preliminary development work, some of which gives some promise of success.

YUKON

Gold Declines; Silver Increases.—In placer gold mining, the Yukon Territory, it would seem from the reports of recent arrivals from Dawson, is losing ground. While this is so and although there is no present indication of its regaining the position established by the Klondyke discoveries of over 25 years ago, the Mayo silver finds assure the Yukon of a bright future as a silver producer.

Such is the opinion of those who have spent the summer investigating mining conditions in the Territory. It is said that there have not been more than 800 men engaged this year on the creeks adjacent to Dawson. At Mayo alone there were at least 500 at work in or about the silver mines. Nothing could tell more clearly the story of the decline of one and the progress of the other form of mining in this territory.

Concentrator for Keno Hill.—The hope of the Yukon lies in its newly discovered high-grade silver ores. The attention of mining men is centered in the development of these deposits. The Treadwell Mining Co. and the Guggenheims are proceeding with confidence with their plans for large scale operations. Authoritative report has it that a concentrator is to be installed on Keno Hill and that greater shipments of the product of the camp may be expected next year. The proposal is to ship without treatment only the selected high-grade material, and to add to that the concentrate from the lower grades.

Difficulties of Navigation.—Only those familiar with the Yukon can appreciate the difficulties presented by the problem of transportation. The Stewart River, down which the ore from Mayo is carried, is navigable only at high water, and high water prevails for but two, or at the most three, weeks in the Spring and Autumn. In the Spring it is necessary to transport the ore, which has been brought to the river bank over the snow during the winter, as far as the main waterway, whence it is taken to Ninano, thence by rail to Seward, and thence by ship to the Selby Smelter, California, where it is refined.

Between 8,000 and 9,000 tons of ore are reported to have been shipped this year. It can be imagined what a rush there was to get it down to Stewart River during high water. Arrivals from Dawson tell of seeing the ore piled along the river bank at the mouth of the Stewart River where it was left in order that barges might return for more, and also state that the same rich, silver-bearing ore was scattered along the streets of Dawson while waiting trans-shipment.

Dam Being Built.—This is a haphazard and unsatisfactory method of transportation. Something safer and more expeditious is necessary if the possibilities of Mayo are to be fully realized. Herbert Wheeler, general manager of the White Pass & Yukon Railway Co., which company owns and operates the bulk of the river transportation, appreciates the imperative need of improvement. In an endeavor to bring this about he has started the construction of a dam below Marsh Lake

near White Horse. At the point selected the river is approximately 300 feet wide. The idea is to hold back the waters of Marsh, Bennet and Tagish Lakes, as well as those of tributary waterways, in order that a tremendously increased pressure of water and ice may be released at a selected time early in the year. The design is to clear Lake Laberge of ice, by directing at it and its tributaries the connected forces of the upper waters, two or three weeks earlier in the year. In a word, Mr. Wheeler aims to open Yukon inland navigation about May 15th instead anywhere from the 1st to the 15th. of June each year. In the natural course of events, as experience has shown, navigation is impractical until some time early in June. If Mr. Wheeler's plan works out it will lengthen the Yukon transportation season some two or three weeks. It will make transportation from Mayo, down the Stewart River, much more economical because it will mean that the larger rivers and lakes will be open at about the same time as high water comes on the Stewart River, thus permitting an uninterrupted flow of ore from the mining camp and, of course, the equally free transport of supplies in to the camp.

The experiment is being watched closely throughout the Yukon. Many are sceptical, but Mr. Wheeler and his associates are confident of its success. All, however, are agreed that the benefits promised are worth striving for and that it will be a boon to the Mayo camp if May 15th can be depended upon each year as the date of the opening of Yukon navigation.

ALBERTA

New regulations have been passed by the Government of the Province of Alberta which aim at preventing the substitution of an inferior for a high-grade coal. The text of these regulations follows:

1. Every operator of a coal mine in Alberta shall have a registered name for his coal and all coal shipped by such operator shall be shipped under such registered name.

2. Every operator of a coal mine in Alberta shall state on every invoice and shipping bill governing shipments of coal from such mine and on a card which shall be prominently displayed on the car door:

(a) The name of the mine from which such coal is produced and the registered name of the coal;

(b) The district in which such coal is situated;

(c) The name and size of the grade coal;

(d) The date of shipping such coal and its destination.

3. Every dealer, whether wholesale or retail, selling coal produced in Alberta shall state on every bill weight ticket or invoice covering sales of such coal:

(a) The name of the mine from which such coal is produced and the registered name of the coal;

(b) The district in which such coal is located;

(c) The name and the size of the grade of coal;

4. Every dealer, whether wholesale or retail, selling coal produced in Alberta, shall keep a record in his office of the amount of coal purchased and sold from each mine under the registered trade name of the coal, such record shall also include the name and the size of the grade purchased and sold and to whom it is sold.

5. All coal advertised and sold shall be advertised under its registered trade name.

6. The province may appoint an inspector or inspectors to examine at any time within the province or at any other point all coal produced for sale.

7. An inspector at point of shipment shall have power to inspect any coal for the purpose of ascertaining whether the coal conforms with the information contained in the shipping bill or bill of lading and if in his judgment it contains an excess amount of slack or other impurities such information shall be stamped on the face of all documents.

8. An inspector shall have the power to inspect any coal whether in the possession of a dealer, either wholesale or retail or consumer for the purpose of ascertaining whether the coal conforms with the information contained in the shipping bill, bill of lading or weight ticket and whether the coal contains an excessive amount of slack or other impurities.

9. Any operator, broker or dealer, who falsely designates the trade name of the coal, the point of origin, the grade or class of coal or otherwise infringes these regulations shall upon summary conviction be guilty of an offence punishable by fine or imprisonment for a period not exceeding six months or to both fine and imprisonment.

BRITISH COLUMBIA

Mineral Rights on Vancouver Island—To eliminate the present unsatisfactory dual control of minerals lying within the boundaries of the 2,000,000 acres on the east coast of Vancouver Island and known as the E. & N. Ry. Land Belt, has been the ambition of Hon. Wm. Sloan, provincial Minister of Mines, for years.

The present situation is that the gold and silver within this area is vested in the Crown while the base metals and the surface belong to the E. & N. Ry. Co., which is a subsidiary of the Canadian Pacific Ry. Co. The prospector, when staking a mineral deposit within the Belt, must conform to the terms of the Mineral Act as far as the precious metals are concerned and, in order to exploit the base metals, must come to terms with the Railway Co. This means that he is required to pay to the Company as a rule some form of royalty on the copper, zinc or other metals produced, outside of the precious metals. It is considered by Mr. Sloan, as well as by most mining men that this condition is holding up development on the Island and is one that must be removed with as little delay as possible.

Some two or three years ago the British Columbia Department of Mines took up the matter with the Company's officials, making a proposition which may be summarized as follows:

"That, as regards the mineral rights of the E. & N. Ry. Belt remaining unalienated, the Government is prepared to go practically into partnership with the Railway Company.

"The District to become fully under the operation of the Mineral Act as far as underground mineral rights are concerned; that such mineral rights be administered by the Government; that the cost of such administration be entirely borne by the Government and that the gross receipts of all revenue received by the Government from and on account of such mineral rights including taxes, etc., be divided equally between the Government and the E. & N. Ry. Co."

Following this suggestion the Company stated that, before proceeding with the dicussions, it was desired that time be allowed them to make a thorough mine-

ral survey of the Land Belt. The Department of Mines acquiesced and it was announced that the work of this exploration had been placed in the hands of engineers associated with the Consolidated Mining & Smelting Co., another subsidiary of the C. P. R.

Now it is stated that the work of the Consolidated Mining & Smelting Co., in the section of Vancouver Island in question is practically concluded. Consequently the recent visit to Victoria of E. W. Beatty, President of the C. P. R., afforded the Hon. Mr. Sloan, an opportunity to press for a resumption of negotiations with a view to settling of the matter. Mr. Sloan had an interview with Mr. Beatty on the subject and was pleased with the result. He is inclined to believe it may be possible to arrive at an adjustment that will be mutually agreeable.

Premier Dividend. — A. B. Trites, of Fernie, is authority for the statement that the Premier Gold Mining Co. decided to distribute another dividend of $400,000 on or about September 30th. This will bring the total dividends, since the first was authorized in 1921, up to $4,450,000. Since the first dividend was paid in the year mentioned, which was at the rate of 8 per cent. on a share capital of $5,000,000, the Premier Gold Mining Co. has not passed a quarterly dividend.

Progress at Indian Mines. — G. B. D. Turner, managing director of the Indian Mines Ltd., states that a contract has been entered into with Boyle Bros., of Spokane, for 2,000 feet of diamond-drilling on the property of the Indian Mines Ltd., which is situated in the Portland Canal Mining Division northwest of the Premier Gold Mining Co's holdings. The Provincial Government has been constructing a waggon road to the property this summer. The road will open up not only the Indian Mine, but a number of other promising prospects in the same section. Mr. Turner explains that the drilling, which starts immediately, as the plant already is on the ground, is to prove up ore-bodies upon which there has been considerable surface and underground development. He asserts that sufficient information has been obtained to justify an enlarged scope of operations, large bodies of milling ore having been uncovered and only last month a new ore-body having been opened up in No. 1 tunnel. After the drilling it is proposed to build the first unit of a concentrator with an initial capacity of 150 tons daily. The installation of an aerial tramway also is under consideration. Mr. Turner makes the following general statement:

"Briefly it may be stated that the Indian Mine main veins are very persistent and extend in a general northerly and southerly direction along an intensely fractured zone. This zone cuts across the general strike of the country rock at a narrow angle. Bedded deposits are occasionally found. An average sampling across 26 feet assayed $25 per ton and other samples point to this as the average value."

Alice Arm. — The Esperanza Group of mineral claims, Alice Arm, not far from the Dolly Varden Mine, is reported to be growing more encouraging with development. This summer a small vein of high-grade ore has widened considerably as work has proceeded. At the point now reached it is three feet wide and high assay returns have been obtained. Four hundred sacks of ore are ready for shipment and two tons a day are being added.

The Homestake Mining Co., whose work has been facilitated this summer by the use of the Dolly Varden Railway for transportation, is installing a compressor on its property at Kitsault Glacier. The plant is capable of operating two drills. It will be driven by gasoline and the work will go forward all winter.

The Rex Group of mineral claims, which runs to the Dolly Varden Ry., has a promising surface showing, a four-foot vein having been uncovered that is traceable for 1,500 feet. Assay returns are not yet reported.

Government Engineer Inspects Upper Peace River. — Coal, iron, and placer gold deposits of the Peace River country, northeastern British Columbia, were examined by J. D. Galloway, government mining engineer, in the course of a tour of that territory from which he has just returned. With regard to the coal deposits, he says that they are situated at Rocky Mountain Canyon, that they extend over an area of 40 by 60 miles, and that there are a great many seams, most of them small but quite a number having commercial importance. The coal is semi-anthracite, similar to that of the Groundhog district of northwestern British Columbia, and runs very low in ash. Mr. Galloway believes that, as far as quality is concerned, it could compete successfully with the anthracite coals of Pennsylvania in the markets of the Province of Ontario. One shipment of 40 tons was made by scow to Peace River Crossing, where it was turned over to the C. P. R. to test. It is reported that the results were very satisfactory.

As to placer mining, Mr. Galloway found two companies operating with dredges. They had not, however, met with much success and a different kind of plant will be necessary to secure a higher recovery. Individuals working by hand are doing fairly well, as the Peace River sands carry much fine gold and a considerable value in platinum. Mr. Galloway says, however, that it is low-grade ground and that the dredging operations will predominate eventually.

Trail Ore Receipts. — Ore receipts at the Trail Smelter, Consolidated Mining & Smelting Co. for the week Sept. 8 to 14th inclusive totalled 3,500 tons made up of shipments as follows:

	Tons
Company Mines	2,929
Cork Province, Zwicky	39
Knob Hill, Republic Wn.	52
Lone Pine, Republic Wn.	218
Paradise, Invermere	41
Quilp, Republic Wn.	120
Silversmith, Sandon	33
Whitewater, Retallack	68
Total	3,500

Kaslo Mines Consolidated. — At a recent meeting at Kaslo of the shareholders of the Whitewater Deep Mine it was decided to consolidate with the Whitewater Mine. Major J. L. Retallack, one of the chief owners in both properties, states that it is the intention to proceed with development. W. H. Burgess, of Kaslo, was appointed managing director. R. H. Stewart, it is said, has made a favorable report as to the possibilities of the consolidation and future operations will be under his direction as consulting engineer. The Whitewater Mine is one of Kaslo's banner producers.

having paid over $600,000 in dividends and disbursed another $1,250,000 for wages and supplies.

High-Grade Ore at Windpass. — Developments at the Windpass Mine, near Chu Chua, in the Kamloops district, continue to be satisfactory as is indicated by the fact that A. B. Trites is reported to have bonded the adjoining Red Top Group of claims. The Windpass, it is reported, has uncovered a 12 foot seam of high-grade ore at the 100-foot level Additional machinery is being installed on the property and its operations will be continued on an extended scale during the winter.

Prosecutions for Law Infringement. — Breaches of the Coal Mines Regulation Act of British Columbia continue to engage the attention of the Police Courts and of the officials of the B. C. Department of Mines. For the most part these infractions of the law are of a minor character but are considered of importance because of their danger, if persisted in, to the lives of those at work underground. One such incident occurred recently when John Nigro, a coal miner, fired shots in the Granby Mine, Cassidy, in contravention of the terms of General Rule 12 of the Act. He was found guilty by the Magistrate and fined $10 and costs. Hon. Wm. Sloan, Minister of Mines, was of the opinion that there should be a more thorough investigation and ordered W. H. Wall, of Nanaimo, to conduct a special inquiry. This has been done and whether further steps will be taken against Nigro will depend on Mr. Wall's report.

Winning First Aid Team. — The coal mining centre of Cumberland, Vancouver Island, is proud of the success of its representatives in the First Aid and Mine Rescue Competitions held recently at Ladysmith. In a reception the Mayor, officials of the Canadian Collieries (D) Ltd., and the citizens generally united in congratulating the winning teams. One of the special features of the occasion was the presentation to A. J. Taylor of a fountain pen by Mrs. Walter Hudson, captain of Cumberland's first aid ladies team, on behalf of the members of that team. It was said that they owed their success and their high state of efficiency to the coaching of Mr. Taylor. In a number of addresses the importance of a thorough knowledge of the principles of first aid and mine rescue work in a coal mining community was stressed.

Self Rescuer. — Another interesting test of the Self Rescuer Apparatus, recently put on the market by the Mine Safety Appliances Co., took place at Cumberland recently. It was conducted by the B. C. Department of Mines and is said to have demonstrated satisfactorily the usefulness of the apparatus in an atmosphere heavily charged with carbon monoxide, providing there remains enough oxygen for the maintenance of life.

It was about electricity — in its earliest days.

"But after all," protested Gladstone, "What use is it?"

"Sir," said Faraday, "there is every probability that you will soon be able to tax it."

"Ah! Ah!" said Gladstone.

So to the practical man, who in these days of urgent economy must scrutinize closely every proposed expenditure of Government, the real economy of a wise expenditure on Scientific Research in connection with Canadian agriculture and industry of all kinds, is indicated by the stories of what research has accomplished.

NOVA SCOTIA

A Farewell Dinner. — At the invitation of Mr. D. H. McDougall, retiring vice-president of the British Empire Steel Corporation, the district superintendents and the mine managers of the collieries, the heads of the different departments, and a few other friends enjoyed a supper and a social hour together in what is known as "Tom Brown's bungalow." The beautiful grove, the rustic bower, the silver light on the lake, the lodge of ample size, beautiful in structure and device, the gathering of friends and the hearty greeting and glad handshake of Mr. McDougall acted like magic on the Celtic spirit, and when the stirring strains of the bagpipes struck up, passions swayed and the men of Glace Bay, New Waterford and Sydney Mines danced out in perfect rhythm the many steps of the good old Highland hornpipes so dear to Hie'lan hearts. Under the tall rock pines restraint was flung to the winds, good fellowship prevailed and in this happy mood all entered the enchanted hall and sat down to a good man's feast.

It was easy for Mr. McNeil, general superintendent of mines, who never fails to catch the spirit of any such gathering, to carry the program through to a very successful finish, and in that care-free spirit which gives the liberty of speech so necessary to full enjoyment, a very pleasant night was spent. In a few well chosen words, he told of the object of the gathering, of the desire of Mr. McDougall to bid farewell to the friends who had worked with him and who had rendered him most faithful service. He stated that all were free on that night to express their sentiments towards Mr. McDougall, and they intended to do so.

Mr. McDougall's Remarks. — After prolonged applause of Mr. McNeil's remarks, Mr. McDougall in a few measured and well thought-out remarks told of the pleasure this meeting brought to him. He had been associated with a large number of the men here for many years. Indeed some of them he had known all his life, and had always enjoyed their friendship and confidence. He had seen these men tested and tried, and well knew what they were capable of doing under any circumstances. He had watched them accomplish the impossible, — not the impossible to them, but to those who said it could not be done. There was nowhere in this wide world a finer body of men, and tonight he placed them second to none anywhere. The British Empire Steel Corporation had been attacked continually by sinister and subtle forces, vile and vituperative propaganda had been circulated broadcast against them, all the destructive forces of the country had been marshalled to assail them, but in the midst of it all and through it all the officials of the coal company had stood true to their duty and had acquitted themselves like men. It was a hard and trying experience, but in this refining furnace the dross had all been consumed and only the gold left. The excellent condition of the collieries is altogether due to their efforts, he said:

"The coal and steel industry of Nova Scotia," said Mr. McDougall, "is a big business and means much to this Province and to the Dominion of Canada. Upon its success depends much of the prosperity of the country as you all recognize. It is bigger than any one man, or all of us together, and I ask you, my friends here, to give your best service, your energy and ability to the corporation operating these industries. As in the past

you have been devoted to duty and loyal to the cause of the corporation and have labored unceasingly to advance its interests, so I ask you to continue to carry on as you have been doing, to transfer your allegiance to my successor, whoever he may be, and loyally to stand by him, and you will remain my friends more than ever. He will need your hearty support, all your united efforts for with the 23,000 men employed in the different parts of the district, there is a tremendous task ahead. You have within you the great asset to help him; that is skill, knowledge and dependability of character. It will be his to command, and yours to give, and I know you will give heartily. I am leaving the corporation with the good will of all in it; I bear no ill-will to any person, and in this happy state of mind I retire from the service.

"Your gathering here today is one of my happiest moments, for I realize more than ever before how I have been surrounded by real men, whom it was good to meet, to know and to labor with. I only wish it were possible to meet all the employees personally, at this time when such a meeting would not be misunderstood.

"I will still be in touch with your affairs, as I am not severing my connection with the corporation. I may have the pleasure of meeting more of you oftener than before; but I am glad to know when leaving that I retain your good will and friendship, which is an enduring possession."

Reply on Behalf of Staff. — After the singing of "For He's a Jolly Good Fellow" and a song by Mr. Maxwell, Mr. A. S. McNeil replied on behalf of the general staff. Mr. McNeil was reminiscent in mood and recalled past services and relationship. He dwelt on the personal characteristics of Mr. McDougall, his natural kindness of heart and friendly disposition. It was impossible to know him intimately and not to like him. As an official he served better because he felt that his services were appreciated. Men do serve better when they know this. They are inspired with courage, and the higher qualities such as devotion to duty, and loyalty to person are developed. Service tends to the steady growth of friendship. Someone has said that the most perfect friendship is found between superiors and inferiors. It is seldom found among equals, where the green eyed ogre of Jealousy and the deadly hatred of rivalry finds congenial food. Friendship is a plant of slow and cautious growth, and has its roots deep in the soil of the human heart. The storms of life cannot uproot it, and each succeeding gale only causes it to strike farther down to the very foundations of life. Such is the nature of our friendship, said Mr. McNeil. He stated that he had shared much of Mr. McDougall's confidence and anxieties caused by labor disputes and other troubles relating to mining. He had been true to him, and had given of his best and if at times this service seemed to fall short of what was expected it was because he could do no more.

Mr. McDougall had pledged all here tonight to allegiance to his successor in office; he had pointed out the path of duty, and he wished to assure him that every person present would follow his advice. "Although parting with him, we remain to perform our several tasks as faithfully as while he was with us. We regret, however, that he is leaving and feel that his going is a distinct loss in many ways."

The Presentation. — Mr. H. J. McCann, acting Vice-President, in his usual breezy, off-handed manner, stepped forward and read a well worded address, which voiced the sentiments of all present, and then presented Mr. McDougall with a diamond pin and set of cuff links. Mr. McDougall thanked his friends for this, another token of their good feeling towards him.

Speeches were made by the chief inspector of mines, A. McEachern; G. D. McDougall, Chief Engineer, and many others, which were reminiscent and full of friendship. Some of these referred to the early struggle of Mr. McDougall in rising from the ranks unaided, and the long weary road he had to travel almost alone. Of him it could be said:

"The heights that others won and kept,
Were not attained by sudden flight;
But they, while their companions slept,
Were toiling upwards through the night."

Another Wabana Slope Closed. — Another ore mine has been closed at Wabana. Ore trade just now is fairly brisk and recently several ore cargoes have been shipped to foreign ports, including some to the United States. The ore shovels at the stock piles are kept busy to meet the demand.

No Need for Royal Commission Now. — There is considerable interest and much criticism of the appointment of the Royal Commission to investigate conditions at the Sydney steel works. This arises not so much from the appointment of the commission, as from the late date at which the matter was taken up. It is generally felt that had this effort to find out the truth about the labor agitation at the Sydney steel plant been undertaken last winter in the incipient stages of the dispute, it would have accomplished something. It is difficult to see what good it can now do, seeing that the employees and employers on the plant are working in unity.

There is slightly more excuse for inquiry into the colliery affairs, which it is proposed by some should be undertaken. The Commission would find in this case distinct evidence of the injustice of the former labor leaders both to their employers and to those workmen who receive low rates of pay. It might be well to have these facts laid before the public by the Commission.

HIGH-GRADE ORE AT DEEP LEVEL

It has been announced by officials of the Treadwell Yukon Company that 400-ounce silver ore has been found on the new 300-foot level of their mine at Keno Hill, near Mayo. This is of importance, as establishing the continuity of high values to that depth.

HAFNIUM

In discussing the newly discovered element hafnium recently in England, one of the discoverers, Dr. G. Hevesy, pointed out that, though its place in the periodic table is between zirconium and thorium, its chemical characteristics show that it has a close relationship to the former.

BOUNTY ON AUSTRALIAN SULPHUR

Because the domestic production of sulphur is regarded as a national necessity, the Australian Parliament has voted £100,000 a year to provide a bounty of £2. 5s. per ton on all sulphur produced in the Commonwealth from local pyrites. The free importation of Louisiana sulphur recently caused Australian pyrites mining to cease.

Graphite, by H. S. Spence.

Gas Producer Trials with Alberta Coals, by J. Blizard and E. S. Malloch.

The Mines Branch maintains the following laboratories in which investigations are made with a view to assisting in the developing of the general mining industry of Canada:—

Fuel Testing Laboratory.—Testing value of Canadian fuels for steam raising and production of power gas; analyses, and other chemical and physical examinations of solid, liquid and gaseous fuels are also made.

Ore-Dressing Laboratory.—Testing of Canadian ores and minerals, to ascertain most economical methods of treatment.

Chemical Laboratory — Analyzing and assaying of all mineral substances and their manufactured products. Copies of schedules of fees, which are slightly in excess of those charged by private practitioners, may be had on application.

Ceramic Laboratory.—Equipment is such that complete physical tests on clays and shales of the Dominion can be made, to determine their value from an economic standpoint.

Structural Materials Laboratory.—Experimental work on sands, cements and limes is also undertaken.

Applications for reports and particulars relative to having investigations made in the several laboratories should be addressed to The Director, Mines Branch, Department of Mines, Ottawa.

INDEX TO MINE AND MILL SUPPLIES

Addresses of advertisers whose names appear in the following classified index, may be found upon reference to their advertisements. An alphabetical index to advertisers will be found on the page facing the inside back cover. The following regulations apply to all advertisers: — One-eighth page, every issue, three headings; one-quarter page, every issue, six headings; one-half page, every issue, twelve headings; full page, every issue, twenty-four headings. Buyers who are unable to find in the classification here given such machinery or supplies as they desire are invited to write Service Dept., Canadian Mining Journal, Gardenvale, Que., who can, in all probability, refer them to proper sources.

1-R 550 Leyner Sharpener at the Lake Shore Mine. This is the second Leyner Sharpener installed at this mine.

LEYNER DRILL STEEL SHARPENERS

Cut Drill Steel Costs - Reduce Drill Repairs

"*Leyner*" Sharpeners have stood the test of time. The proof of their work is the money and time saved, not only in forging bits and shanks, but in reducing drill upkeep costs.

Operated by compressed air, with single lever control, these machines offer the most modern, rapid and economical method for bitting and shanking steels. Their construction guarantees bits which are uniform, having true cutting edges and proper tapers.

"*Leyner*" — made steels require, in many cases, only 1/16 in. variation in bit diameters on successive lengths. This greatly reduces the amount of rock to be cut and allows the holes to be bottomed at the required diameter.

"*Leyner*" Sharpeners reduce the wear and tear on drills. Incorrect bits cause rifled holes and severe strain on the rotation parts. Poor shanks produce cupped and broken pistons, and excessive wear on chucks.

The latest model Sharpener runs much faster and easier on account of being fitted with valveless hammer cylinder and piston type throttle valve.

This new hammer cylinder and throttle valve are adaptable to old style machines.

Insure against trouble and lost time by installing the "*Leyner*" Sharpener.

Bulletin No. K-201-B will tell you the complete story. Send for it. It's just off the press and is replete with information that you should have.

Ontario's Minerals

PROVINCE OF ONTARIO

Hon. CHARLES. McCREA, Minister. DEPARTMENT OF MINES *Thos. W. Gibson*

Mineral Areas

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favourable for the occurrence of minerals 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver veins of Cobalt, Gowganda and South Lorrain occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

Economic Minerals

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario: — actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluorspar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, Portland cement, brick and tile, meet every demand.

Mineral Production

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1922 to be worth $62,202,169, of which the metallic production was $38,190,711.

The following figures show the growth of Ontario's mineral industry by five-year periods since 1891 when a Bureau of Mines was first established.

Year.	Value.	Year.	Value.
1891	$4,705,672	1911	$41,976,797
1896	5,235,003	1916	65,303,822
1901	11,831,086	1918 (Maximum war output)	80,308,972
1906	22,388,383	1921	48,128,387
	Dividends.		

Dividends and bonuses paid to the end of 1922 amounted to $28,096,699 for gold mining companies, and $86,238,185 for silver mining companies or a total of $114,334,884.

Mining Regulations

A miner's license costs $5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of $2.50 or $3.00 per acre, depending on location in unsurveyed or surveyed territory.

Assay Office

The Provincial Assays Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

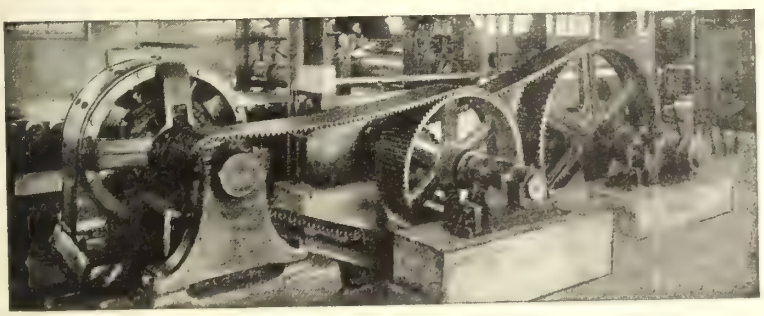
MORSE CHAINS

THE MORSE "ROCKER JOINT"



A few of the Morse chains in use at the Raymond Lead plant

Using chain drives speeds up production, cuts belt expense and overtime wages and operates with practically no repairs.

Write for Booklet

CANADIAN AGENTS

Jones & Glassco, Regd.

MONTREAL, TORONTO.

O.W. Ludwig, *Plant Superintendent of the Raymond Lead Co., Chicago, says:*

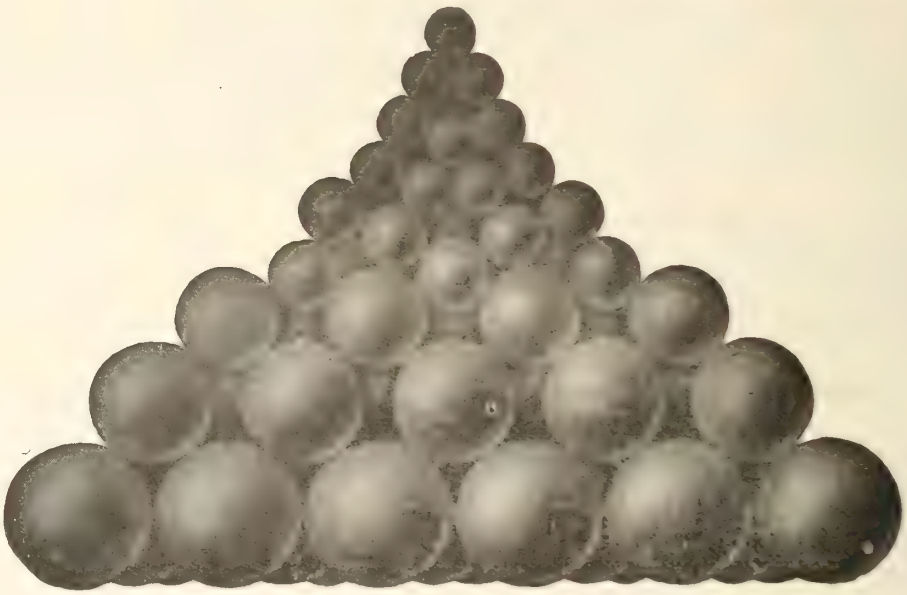
"Thirteen years of service without a repair is our experience with two 100 H.P. and ten 20 H.P. Morse Silent Chain Drives.

"When we moved into our present plant thirteen years ago, we installed the present Morse equipment of silent chains for our two lead mills and ten hydraulic pumps. We had always previously used leather belts, but not without considerable trouble. For instance, if the operator was not careful—and gave the motors too great a load, the leather belt would slip and in some cases burn out. While with the Morse Chain Drive we overload them at times up to 15 H.P. without the slightest trouble.

"When we used leather belts on the hydraulic pumps, if a pump packing suddenly gave way, the water would squirt all over the pump as well as adjoining pumps, causing the leather belts to get wet. This often necessitated a shut-down on 3 to 4 pumps to dry out each belt, thus causing a loss of time by the men which resulted many times in paying overtime to catch up on the work. Of course, with our Morse Chain Drive we have no such trouble—this positive drive prevents slippage and is not affected by water.

"Leather belts lasted us 2 to 3 years at the most, while our Morse Chain Drives have already lasted 3 to 4 times that long and seem good for many more years. So Morse Drives have cut our expense materially, speeded up production, cut out overtime wages and saved floor space, for they operate on shorter centers."

Decrease your grinding costs.



USE HISCO BALLS

"If quality counts use 'Hisco' Products" ***Hisco Balls*** **are noted for superior quality. They are in use in the largest ore and cement mills from Halifax to Vancouver. Forged from Electric Furnace chrome steel, absolutely the best ball on the market.**

Sizes 3, 4, 5 and 6 inch carried in stock.
Special sizes from 6 inch up made to order.

Assisting in the Development of the Mining Industry

It is essential that the peculiar banking needs of those engaged in the exploitation of Canada's natural resources be met with special facilities.

The Imperial Bank, ever a constructive element in the progress of Canada, long since realized the need for interested financial service to enable the proper development of the mining industry.

By opening branches throughout the mining districts and continually adding to them, as necessitated by expansion, this Bank has materially assisted in the development of the industry throughout Canada.

Those whose business is mining will find our facilities adequate and our knowledge of conditions valuable.

IMPERIAL BANK OF CANADA

Peleg Howland, President. A. E. Phipps, General Manager

When a buyer purchases anything for commercial purposes, he does not want to finance an experiment.

There is nothing new about the KROMHOUT Oil Engine and there can be no speculation as to it reliability

TELLURIDES IN THE GOLD BELT

In the gold belt of northern Ontario and Quebec, tellurium is, rightly or wrongly, considered almost as highly as gold itself. Its characteristic occurrence is in combination with gold, so that the word "tellurides" in common parlance means tellurides of gold. It may be of interest, therefore, to trace the history of some of the known occurrences of tellurides in that area.

Tellurides were first discovered in the north country by Dr. Robert Harvie in the course of his field work for the Quebec Bureau of Mines in 1910. He found the mineral in a vein of quartz and ankerite three to five inches wide in a pit on the shore of Lake Fortune, as a small nucleus associated with a liberal amount of visible gold. The principal gold-tellurium mineral was determined as petzite. With it was associated also tourmaline and pyrite.

It is worthy of note in this connection, by the way, that the Quebec Bureau of Mines during the years 1910, 1911 and 1912 conducted the only vigorous campaigns of field work during its history. The reorganization of 1909 was followed by the three seasons of field work in the Harricanaw, Chibougamou and other regions of the north, and in Gaspé. Unfortunately the vigour of this régime ended suddenly at that point. Now, after twelve years of inactivity, there are definite reasons to hope that a renewal of this activity will take place in the near future.

At the time of the mineralogical find at Lake Fortune, it was reported that argentite had been found in the Powell claim in the newly discovered Porcupine camp. On Dr. Harvie's advice, Mr. A. G. Burrows, who had reported on that area for the Ontario Bureau of Mines, examined the reputed argentite and found that it was really telluride of gold. This stimulated a search for tellurides in all the gold veins of the countryside, and in a number of instances the silver-grey minerals that had been called galena, grey copper ore, argentite and what-not were found to contain tellurium and gold. Notable among these occurrences are the Miller-Independence at Boston Creek and the "main break" at Kirkland Lake. The popularity of tellurides among the prospectors at that time is shown by the use of their names for claims, of which the Sylvanite mine at Kirkland remains well known.

Now there come rumours of further occurrences of tellurides in Quebec. There is a mineral found in the recently discovered ore zone on the Noranda property that looks like galena, but has certain abnormal characteristics. It might be well to describe first the ore in a general way. It comprises a zone of rhyolite tuff whose finer fragments and interstitial dust have been replaced by quartz, carbonates and sulphides, the last principally pyrite, with a small amount of chalcopyrite. There is also tourmaline. Later than the pyrite, the galena-like mineral has been deposited, and with it the gold. Some of the crystals of pyrite are coated with thin films of precipitated gold. The "galena" has been examined in a preliminary way by Dr. Harvie and others, and has been found to contain less than the normal amount of sulphur. Also, its cleavage and other physical features are not those of galena. It remains to be determined by chemical analysis whether or not it is a telluride.

It would seem that wherever a soft, grey mineral is found in vein-matter or suspected gold ore near the Temiskaming sediments, it should be examined to find whether or not it is a telluride. One such instance is on the Stabell property, west of Lake Demontigny, whose ore is described in the Quebec Bureau of Mines report for 1919 as containing galena. Few of our field geologists or mining engineers are sufficiently well versed in the niceties of mineralogy and of micro-chemistry to determine exactly what these specks of grey mineral are. So long as we suspect that the presence of tellurides in a gold deposit, like tourmaline, increases its chances of containing workable ore, it will be worth while to submit to expert examination all such occurrences of soft, grey metallic minerals from the gold belt.

HOLLINGER'S POWER DEVELOPMENT

Last week we printed inadvertently in our correspondence pages a paragraph describing the work under way on the Island Portage power development on the Abitibi River that did less than justice to the Hollinger management; in fact it might be construed as unduly critical. We wish, therefore, to describe briefly today the present status of the work.

As was announced some weeks ago, the contract for the construction of the dam, power house and subsidiary structures has been let to Sir William Arrol & Co. On October 1st they took over the buildings at the dam site from the Hollinger officials and put their workmen on the actual construction, which is being pushed as fast as can be, almost regardless of expense. The engineers of this company are confident that they will have their part of the work ready for August 1st next. The Dominion Engineering Company, who are

building the turbines, and the Canadian General Electric Co., who have the contract for the generators, likewise have undertaken to provide their share of the equipment soon enough to allow of operation by that date. The plan of the switchboard, which is an extremely complicated piece of designing, has not yet been completed by the consulting engineers, Messrs. Kerry and Chase. As soon as this is done it also will be put under construction. There has been some slight difficulty in letting a contract for the power line to Hollinger Mines, but there is little likelihood that its construction will lag behind that of the power plant.

Before operations at the dam can be got into full swing or any large amount of material delivered at the site, it will be necessary to complete a three-mile spur line connecting it with the T. & N. O. Railway. No effort is being spared, therefore, to finish this spur line, and its construction has been well advanced during the few weeks since operations were commenced.

If this 20,000 horsepower power plant should be in operation by the first of August next, as has been undertaken by the various contractors, it will constitute very nearly a record for such a formidable piece of construction. Hollinger Mines have much at stake in it, as a much increased daily production of gold awaits only the provision of additional power. It is a wise economy that has directed the management in speeding up the construction of their power plant at the cost of the additional expense that always accompanies abnormally quick building.

AIDING ALBERTA'S MINERAL INDUSTRY

The annual report of the Scientific and Industrial Research Council of Alberta for the year 1922, recently published, draws attention once more to the fact that, although the mineral resources of the province remain vested in the Dominion Government, a vigorous and rapidly expanding organization has been established in Edmonton to aid and direct the development of these resources. It may be noted in passing that the foundation for this important organization was well and truly laid by Hon. Charles Stewart, Minister of Mines at Ottawa, when he was premier of Alberta.

This Council is composed of the Provincial Secretary, as chairman, the Chief Inspector of Mines, and the President and a number of the teachers of the University of Alberta. The Council employs a technical staff, engaged almost entirely on research in the field and in the laboratories. Gradually an adequate laboratory equipment is being assembled for work on coal, road materials, forest products and other natural resources. There is close coöperation between the Council and members of the university staff, many of the latter being employed by the Council for part of their time.

As Alberta is one of the world's chief repositories of coal, the Council's work is principally concerned with fuels, ranging from lignite to the excellent semi anthracite found towards its western border. Continuously there are under way tests to determine the quality of this coal from the numerous active fields and likewise investigations into the best ways of using it. Boiler trials, tests of smithy coals, trials in domestic furnaces of standard and of new design, and an attempt to solve the problem of carbonizing and briquetting low-grade fuel, are among the duties with which Mr. Edgar Stansfield and his staff on fuel research are charged. Satisfactory progress in each of these lines is reported for the year 1922.

Geological investigation is, of course, also concerned chiefly with coal. During the past year Professor J. A. Allan and N. C. Pitcher surveyed the Saunder Creek and Nordegg coal basins, underlying an area of 650 square miles. In addition reputed discoveries of iron ore on Lake Athabaska were investigated, a noticed some months ago in these pages, the prospective oil area of southern Alberta was examined and a soils survey was commenced.

The provision of good road materials is one of Alberta's pressing problems. There is very little rock or gravel available in the province for building roads. At present even the main highways consist of heaped up soil, which makes an excellent road in dry weather, but is reduced to mud when it rains. Mr. K. A. Clark is charged with the responsibility for finding suitable road materials. At present he is investigating the bituminous sands that are so abundant on the Athabaska river. A practical trial has shown that although this material will make an excellent sheet asphalt road or sidewalk, the cost of transporting it in the raw state from McMurray to Edmonton, a distance of almost 300 miles, is prohibitive. It is evident, therefore, that the bitumen must be separated from the sand before shipment. A process for this purpose has been worked out on a laboratory scale and at present is being tested on a small commercial scale, which will determine both its mechanical and its commercial feasibility. Should the experiment be successful a vast amount of road-building material will become available to the province.

There remains, however, the problem of how to use this bitumen in building roads. The usual aggregate, crushed stone or gravel and sand, is not to be had in most localities. The prairie soil is the only abundant material. Mr. Clark has, therefore, tackled the problem of making a good road from mud and bitumen. He has demonstrated the fact that mixtures of these two in certain proportions are water-proof, the bitumen coating the particles of soil and thus stabilizing the whole mass. Now he has under way large-scale tests of a road with a rigid foundation course containing a small percentage of bitumen and a surface completely impervious to water with a larger amount

f bitumen. The successful use elsewhere of bituminiz-d earth mixtures augurs well for the success of the resent important experiment.

This annual report, like its predecessors, demon-trates the fact that the Council and technical staff harged with directing and aiding the use of Alber-a's mineral resources is well organized and is in the ands of vigorous and competent executives and tech-ologists. We hope that soon the Federal Govern-nent will find it possible to give to the province the ull control of her natural resources, and thus enable he Scientific and Industrial Research Council of Al-erta to round out its prerogatives and completely to ulfil its mission.

PREPARATIONS FOR A GOLD BOOM

Extraordinary success has attended intensive pros-ecting on the Noranda and Lake Fortune gold prop-rties in northwestern Quebec during recent months. Similarly honest pick-and-shovel work has disclosed re-deposits in half a dozen other localities so en-ouraging that they compel vigorous and thorough nvestigation. In fact, according to the observation of competent observer whose business it has been dur-ng the past season to examine critically the western art of the Quebec gold area, almost every party of rospectors who have really prospected their ground luring the summer have located gold ore. On the out-ide one hears little of these strikes, except vague umors. Real prospectors do not talk much.

There are now omens of a campaign of publicity, nd duplicity, based on the genuine worth of the Que-ec gold belt, but not necessarily sharing in it. Some nterprising mining stock brokers, who make their iving by distributing to the public mining script that eldom or never has returned an income as dividends, ave bought claims contiguous to valuable properties, bviously with the intention of instituting a stock-elling campaign during the coming winter, when a 'boom'' in gold stock seems inevitable. Almost every lay now one sees the preparations for this boom in rogress. It is not a spontaneous phenomenon; it is rranged principally by men who wish to make use of he excitement to separate fools and their money.

The first move of the mining stock-jobber is either o acquire a strategically located mining claim, or else o incorporate a company at a modest one, two, three, our or five millions for the stated purpose of getting old of such a claim. In most cases it matters not whether this claim covers barren rock or is under a swamp; its location relative to well-known and valu-ble properties must be such as to look well on the nap printed in the prospectus and the newspaper ad-vertisement. If it has real chances of success on de-velopment, so much the better; but that point is im-naterial to most of these gentry.

Meantime the curiosity of the public has been aroused by mysterious paragraphs in the newspapers. One really must admire the stock-jobber for his knowledge of human psychology. He knows exactly how to prepare his public for the grand display advertisements that are to follow. Many are the artful devices that help on the campaign. In fact, the campaign is usually conducted by clever, hard-working men, whose abilities, if applied honestly on behalf of the mining industry instead of in this legalized roguery, would be a very substantial aid.

This is the method of the out-and-out swindler. There are others who mix the mining of the ground and the mining of the public, in proportions that deceive many astute non-mining men. These are more dangerous both to the mineral industry and to the public, for their occasional success in mining the ground, and the consequent return to share-holders (which is still less frequent), provides the wonderful examples of ''get-rich-quick'' whereby the salesmen of bogus stock lure their victims along the 1,000-per-cent-per-annum road to ruin.

There will be dozens of wild-cat gold mining flotations during the coming winter. There may possibly be one or two honest mining stock issues to the public: if so the *Canadian Mining Journal* will try to distinguish them and mention them in these pages. We cannot attempt to keep track of the illicit issues. They multiply like rats, or like the insect pests that likewise batten upon the human species.

It is a pity that present conditions are such that the mining industry must have its counterpart in dishonest mining stock flotations. None other of the basic industries is burdened as is mining with this incubus. Until it is removed (if ever it can be removed completely) the best we can do is to issue a warning periodically, with information as specific as can be set down publicly.

KING-KIRKLAND STILL UNDER OPTION

In our issue of October 5th, in correspondence from the mining districts, we stated that the Tonopah Company had dropped their option on the King-Kirkland property at Kirkland Lake. We have found since then that this is an error; that the Tonopah Company are still pushing vigorously their development of the property, and there is no evident intention on their part at present to stop this work.

The telephone was invented by a great Canadian scientist, Dr. Bell, and Canada has nearly one million telephones, representing a capitalization of $100,000,000. The telephone companies spend annually for research, the results of which are all about us, a sum greater than the total income of many universities, and the enormous amount saved by the use of the telephone is incalculable.

Hollinger Ore Reserves

Estimated at Over $60,000,000, After $72,500,000 Gross Income has been Earned

By ALEXANDER GRAY

The gold ore reserves of Hollinger Consolidated mines will have an estimated gross value of between $60,000,000 and $63,000,000 at the end of this year. The factor of safety always availed of in the annual reports of the company may cause the management to shade to $60,000,000 the grand aggregate of the ore reserves at that date. Already, it may be said, the reserves have climbed to that peak. The formal record, therefore, is merely a matter for adjustment. Directors have assurances to this effect. Their mines are much greater in their immediate certainties than all previous data as to tonnage and values indicated. If the higher estimate of $63,000,000 is registered by General Manager Brigham, then the net gain to be credited on account of 1923 operations will be nearly $30,000,000.

On December 31st, 1922, the gross value of developed ore, probable ore and outcrops was placed at $43,269,827. Putting the 1923 gross income at around $9,500,000—most of it from the mines—the addition of $20,000,000 net to the value of the ore reserves, and the strong treasury, will leave the company alone of its kind on this continent.

Beginning 1924 with an earnings record of approximately $72,500,000, ore reserves of $60,000,000, or more, as the case may be, and with the further intention to push development on a large scale from the 1,700-ft. level, the outlook does not require horoscopic comment. Having upset precedents and surpassed the most optimistic expectations and now promising more than it would be prudent to forecast offhand, the administration and management have to provide power, milling and metallurgical capacity to the economical limit of their mines.

A year hence it is hoped the new power plant will be in operation, and Hollinger's flood-tide of gold will begin to flow. Thirteen years will have elapsed since the first trickle of gold. By then production should be nearing the $85,000,000 mark, despite enshackling power failures, a destructive fire, labor troubles, hardships, incidental to the Great War, and the cost plus involved in surtaxes, and import duties on machinery and supplies. What has happened in the twelve years since milling began bespeaks for constructive mining more consideration than is accorded to it by leaders in finance and business.

Why the Mines Cannot be Crippled

Gold mines that, under the varying circumstances prevailing since the destructive fire of 1911, present their owners with $135,000,000 are sermons in millions, to be taken to heart by those who never devote a spare moment to reflection on what they mean. Gross profits of about $37,500,000; distributions of almost $23,000,000, leaving the treasury fortified to the extent of what may be $7,000,000, but cannot be estimated by the outsider owing to the purchase of the Schumacher property and extraordinary expenditures on power facilities and other plants, make the history of the Hollinger that of a veritable golden era.

In dividends and in what is available in quick assets for dividends, apart from the ore reserves broken in the stopes or still *in situ*, shareholders who held on have in hand or within easy reach 1,000 per cent. on their investment, even though they paid at par for the original capital issue of $3,000,000; besides which there is a market profit of $41 per share, since four shares were given for one of the original. Furthermore, as the issued capital is $24,600,000, and the gross value of the ore reserves is between $60,000,000 and $63,000,000, by including the liquid assets in the treasury it is evident there is around $70,000,000 covering the outstanding capital.

No other precious metal mine in the western world has such a balance sheet, notwithstanding the relative loss due to mishaps of the past years. For every dollar represented in the issued capital here is $2.85 now available. As a speculative investment, therefore, Hollinger securities have continuous rewards for those who retained them when more sapient financiers accepted other paper as collateral, that was infinitely more risky.

Recent developments on what at present may be regarded as intermediate levels—no deeper than 950 feet—make it inexpedient longer to ignore certain of the ore reserves. The practice has been to underestimate those reserves. During the current year, when the mill was compelled to slow down, more power was diverted toward development, hence the anticipated net gain. What part the Schumacher is playing will be stated in the annual report.

1923 Mining and Milling Results

In comparison with the two preceding years, 1923 operating results have been grievously disappointing to the directorate and the management. In 1921 gross income was $10,314,515.31. In 1922 it was $12,824,608.25 On September 9th, with four more four-weekly periods remaining until the end of 1923, the company had milled 887,257 tons, a daily average of 3,535 as against 4,029 in the same periods in 1922. Possibly the total tonnage milled in this year may be over 1,200,000, perhaps nearer 1,300,000. In 1922 the mill treated 1,491,381 tons that averaged $8.53 per ton. The 1923 milling average to September 9th was $7.78.

The gross gold and silver content of the 1923 tonnage dealt with to that date is given as $6,907,647. Of that $6,647,186 was recovered. Adding $107,165 as the premium upon bullion, and $211,405 interest on investments, the gross income for the nine periods was $6,965,753. More power now being available, and likely to be sufficient throughout the closing quarter, the 1923 gross income should not be far from $9,500,000. Whatever it may fall short of that total, will not be the fault of the management. Power shortage could not be surmounted. Failing that, the management alternatively adopted the policy of aggressive development, incidentally placing a greater tonnage of broken ore in the stopes. One section sixty feet wide, and the developments elsewhere, provided "better and better" consolations.

More than 450 men are employed on the company's Abitibi river power development. A year hence Hollinger will be self-contained and the stream of golden metal will be poured out continuously in larger quantities.

A recent British visitor to India, Mr. Wilfred Wyld, remarked on returning that "there is vast unexplored mineral wealth in the country, and anyone who is able to stand the climate and has the inclination can find plenty to do."

Natural Gas and Petroleum Resources of Western Canada

The Manufacture of Carbon-Black — II.

By NEWTON W. EMMENS

(continued from page 799)

Channel Process

This process is the invention of P. J. McNutt, for which he obtained a patent in 1892. It is regarded as one of the most efficient systems and is in common use today.

The difference between this system and the small rotating disc lies in the burner and in the surface upon which the carbon-black is condensed. The latter consists of mild steel channels seven to eight inches wide, weighing 12¼ pounds to the foot, and nine feet long. Eight of these channels are arranged side by side and bolted near each end to transverse channel beams which are supported upon wheels at either end, thus forming a table. This table is supported by a trestle six feet high and sixty-six inches wide along the top of which, at either side, is a steel rail, 16 or 20 pounds to the yard, upon which the wheels run. A reciprocating motion of about five feet is given to these tables by shaft and gears driven from the power house.

Below the channels are located the carbon-black collecting hoppers, which are spaced four feet apart. From them the carbon-black falls into the conveyor that takes it to the bolting and packing house. In these hoppers is arranged the scraper that removes the carbon-black from the channels. There are two classes of scrapers in use; one of them removes the deposit continuously, and the other removes the deposit while the table moves in one direction only. The latter is preferable because it gives a more uniform grade of carbon-black.

Between the hoppers are located the burners. These consist of a ¾ inch pipe into which are set 8 to 10 lava tips. One burner is placed beneath each channel, parallel to, and about four inches below it. The gas is distributed to the burners in such a manner that the flow is uniform to each table throughout the plant. Fig. 3 is a sketch of one of these channel system carbon-black burners.

The other parts of the plant are the same as those used in the rotating-disc process already described.

Plate Process

This process was devised by Godfrey L. Cabot in 1892 and is still being used at a number of plants, notably in West Virginia and Louisiana, although not to the same extent as the rotating-disc and channel systems. There are two modifications of this plate process, both of which employ plates 24 feet in diameter. In one case the plate is stationary while the burners and scrapers revolve beneath it; in the other the burners and scrapers are stationary and the plate revolves. The first method is that most commonly used.

The plates consist of 48 iron segments, arranged in two rows, 16 in the inner and 32 in the outer. These plates have holes in them through which the products of combustion can escape and which enable a draught to be maintained. The plate is supported by a cap, shaped like a truncated cone, resting upon the top of a hollow mast, a series of guys connecting the cap with the outer edge of the plate, the centre of the plate being held in place by a collar secured to the mast. Around the plate is erected a sheet-iron building 26 feet in diameter, and above each is a roof made of corrugated iron that extends about two-thirds of the distance up the mast, leaving in the centre an open space through which the gases of combustion can escape.

The burner consists of about 50 pieces of 1¼ inch pipe set at equal distances apart and extending from the mast to the outer edge of the plate. In these pipes are placed the lava tips, of which there are 1,265 under the entire plate.

The scrapers and collecting box are placed radially on the mast beneath the plates, and in a space between the burners provided for that purpose. From the collecting box the carbon-black falls into a conveyor located on the floor at the base of the mast, by which it is taken to the bolting and packing house, as in the other processes already spoken of.

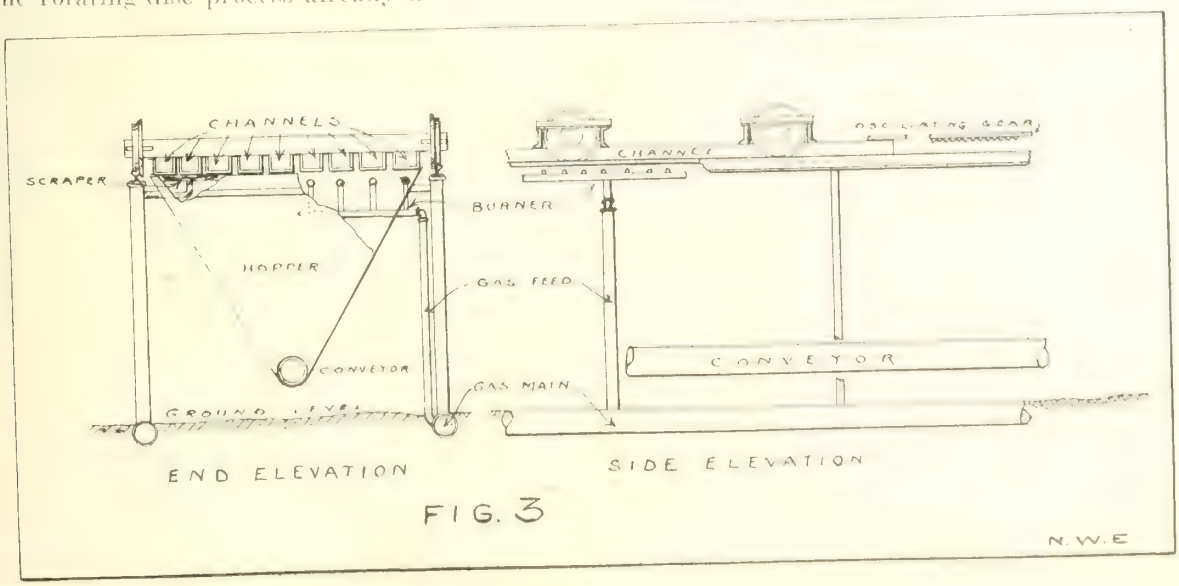

FIG. 3

Roller Process

This process was first tried out in 1883 by its inventor, E. R. Blood, with indifferent success due to the small amount of carbon-black recovered. Later, improvements were made in the process whereby the yield was increased somewhat and a market found for the product, which has properties peculiar to itself that are not obtainable in carbon-black made by any other system. The highest grade of carbon-black made at the present time, which is utilized in the manufacture of special inks for use in lithographing, embossing and half-tone engraving, is made by the roller process, even though the yield per thousand cubic feet of gas burned is materially less than that of the other systems.

The rollers used in this process as the surface upon which the carbon-black is deposited are 8½ inches in diameter and made in three sections, each of which is three feet long. These are set end to end upon a shaft 1½ inches in diameter to which they are keyed, thus making the completed roller nine feet long. When these rollers are made from cast iron, they are machined on the outside so as to present a smooth surface to the flame. In some factories extra-heavy casing or pipe is used, in the place of the cast iron, into the ends of which a spider is fitted to carry the shafting. This arrangement has proved very satisfactory and no trouble has been experienced from warping or scaling of the pipe due to the heat. The burner consists of a 1¾ inch pipe set about five inches below and parallel to the roll, in which are placed the lava tips through which the gas passes to the flame. These lava tips have a round opening instead of the slit as in the burners used in the other processes, resulting in a round flame instead of a fish-tail.

The scrapers for removing the carbon-black deposit are put near the top of the rollers, parallel to and running their whole length. They are in contact with the rollers all the time and scrape continuously.

The rollers are operated in batteries of three enclosed in a sheet iron casing, the lower section of which is V-shaped and acts as a collector for the carbon-black removed by the scrapers. Along the bottom runs a spiral conveyor that takes the product to the packing house. The top of the sheet-iron casing is in the form of a removable hood in which are holes to serve as means of escape for the products of combustion. Fig. 4 is a sketch of one of these batteries.

Each building contains 32 of these batteries of rollers arranged in two rows of 16 each, and eight to ten such buildings constitute a unit.

The rollers are revolved by a gear held by a set screw on the end of the shaft. This gear is operated by a worm on the main drive-shaft that runs the entire length of the building and delivers power to each battery. The speed at which these rollers revolve is governed by the grade of carbon-black being made; it ranges from 15 to 45 minutes per revolution.

The bolting, packing, and other details of the plant are the same as those used in the other processes.

Conditions Affecting Operation

The efficiency of a plant for the manufacture of carbon-black depends upon its general design; the lava tip used; the distance from the depositing surface to the top of the lava tip; the control of the air admitted to support combustion, and the speed of movement of the depositing surface. This last affects the quality of the carbon-black produced rather than the quantity. The proper distance between the burner and the depositing surface depends upon the gas being burned, no two gases being the same in this respect. The gas from some fields in West Virginia requires a distance of three inches between burner and depositing surface, but this distance is entirely too long for the Louisiana gas.

Weather conditions also play an important part in the output of a plant, as wind cuts down the yield by causing the flames to flicker and prevents the steady, quiet, smokey flame so necessary for good work. Heavy rains are apt to cause trouble by wetting the carbon-black, the water leaking into the conveyors, burner buildings, etc., and causing the carbon-black to cake.

The presence of salt water or sulphur in the gas causes trouble because the salt crystallizes, and the sulphur is deposited on the burner tip causing the flame to fork and so interferes with its even distribution over the depositing surface; also the amount of gas passing through the burner is lessened. The pressure at which the gas is fed to the burners is also an important matter and should be closely regulated; it

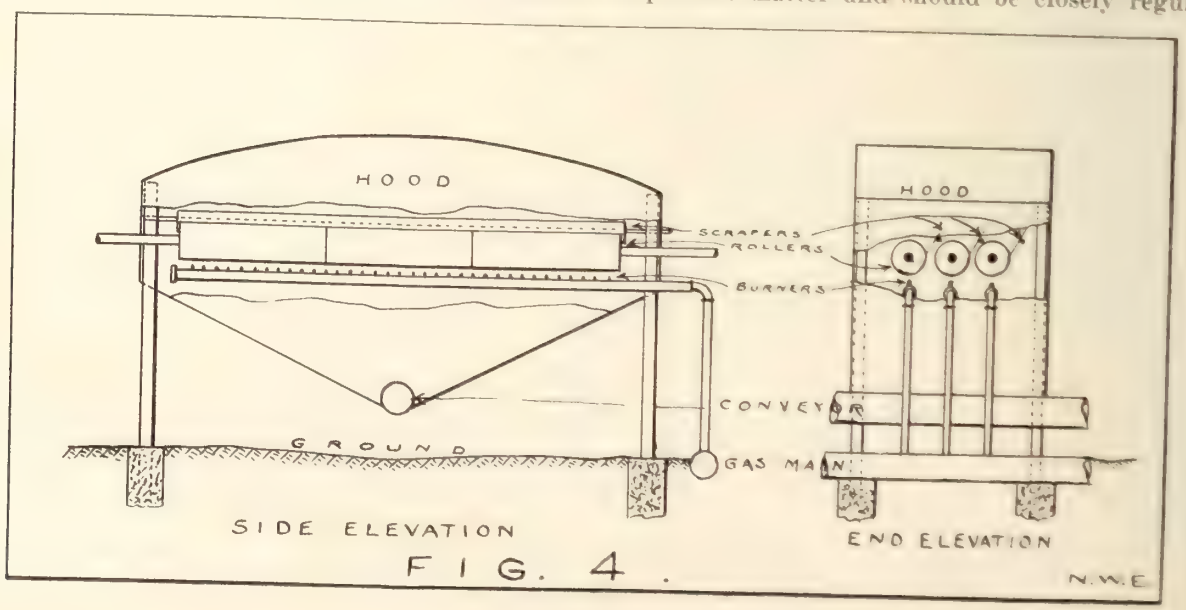

FIG. 4.

ranges from two-tenths of an inch to one and one-half inches water pressure.

Cost of Operation

The cost of operating a carbon-black plant of the small disc, channel or plate type, exclusive of the cost of the gas burned, but taking into account labor, sacking, re-sacking, supplies, and depreciation is $1.00 to $2.50 per hundred pounds of carbon-black produced, (in the United States), the lower figure being that of the big plants. Depreciation is taken at 10 per cent. per annum. A plant having a capacity of 6,000 pounds of carbon-black per day operating in east central Alberta would have a production cost of about $2.25 per hundred pounds, exclusive of the cost of the gas, but inclusive of all the items above mentioned, and making allowance for an increased cost for labor and supplies over the prices paid in the United States.

Natural gas when burned in an atmosphere deficient in oxygen is only partly consumed; the balance of the gas is decomposed by the heat of the flame and the carbon is liberated. If the heat required to decompose the gas can be supplied from some other source, or if the heat obtained from the complete combustion of part of the gas can be applied to another part of it in a more efficient manner than is now obtained in the commercial carbon-black plants, a better recovery can be made.

Attempts to Increase the Yield

Working along this line many experiments have been tried but the resulting product has been of no commercial value because it lacked the valuable properties peculiar to carbon-black, even though recoveries were made as high as ten pounds of carbon from each thousand cubic feet of gas burned. At the present time one of these thermal decomposition processes is being used in connection with the manufacture of hydrogen from natural gas; the carbon formed is of no use and is discarded.

The Bureau of Mines of the United States has carried out a series of experiments with a view to developing a process for the manufacture of carbon-black from natural gas by means of the high voltage arc. The experiments consisted in passing natural gas through an electric arc, the heat of which decomposed the gas and liberated the carbon. While the experiments were very interesting and carbon-black recoveries as high as 6.4 pounds per thousand cubic feet of gas were made, the current consumption was high, ranging from 41 to 94 k.w.h. per pound of carbon-black. In the report on these experiments the following interesting statements are made:

"The amount of carbon-black recovered per unit of volume of gas treated, varies with the current, rate of gas flow and type of apparatus.

"The carbon recovered varied with the rate of flow; the slower the rate of flow, or the longer the gas is exposed to the arc, the greater the percentage of carbon recovered.

"The carbon recovered also varies with the current; the temperature of the arc being a function of the current. As the current is increased, evidently as a result of variation in the temperature of the arc, the carbon yield per unit of volume of gas is increased; this relationship holding within certain values. No carbon is formed when the current is decreased below a certain minimum value. Increasing the current flow produces an increased yield of carbon, but a point is soon reached beyond which an increase in current is accompanied by only a slight increase of black". (From Report of Investigations, Bureau of Mines, Washington, D.C., Serial No. 2417.)

Opportunity for Improvement and for Research

Improvements in the present commercial plants can be made by changing the design so as to reduce construction costs, by making them independent of weather conditions, especially wind, and by the regulation of the air admitted to the burner buildings, which should be more effectively controlled. Such improvements will result in a lessened cost of production and a higher percentage of yield.

The most promising line of research for a process that will give a greater yield of carbon-black from natural gas seems to be thermal decomposition, if means can be found for getting the liberated carbon away from the heated zone as fast as it is liberated, and if the depreciation of the apparatus can be kept within reasonable limits. In such a process the hydrogen liberated could be compressed in tanks and used with the cutting torch, or for the hydrogenation of oils. This problem is well worth the attention of the physical chemist and of the research departments of our Universities and of the laboratory of the Department of Mines at Ottawa.

Some natural gas contains helium, and both methane and ethane can be converted into other products besides carbon-black. These matters will be dealt with in a succeeding article.

"MINING" SULPHUR WITH HOT WATER

The current issue of *Compressed Air Magazine* contains a description of the French method of "mining" sulphur, as used in Texas and Louisana. The method consists essentially of melting the sulphur in the ground by means of hot water, and of pumping the molten sulphur to the surface. To melt the sulphur, water, at a temperature of approximately 330 deg. F., is pumped down into the sulphur-bearing strata lying 1,000 feet or more below ground. As the temperature of the water is practically that of steam at 100 pounds pressure, the water has to be heated and kept continuously under that pressure lest some of it be converted into steam. The water is therefore pumped under the aforementioned pressure into especially designed heaters, where it comes in direct contact with live steam at the same pressure.

After heating, the water is fed to pumps which increase its pressure from 100 pounds per square inch to such a pressure as may be required to force it into the sulphur well—usually from 150 to 200 pounds per square inch. These booster pumps discharge the high-pressure hot water into covered pipe lines which are run from the heating plant to the various sulphur wells scattered over the producing area. One water heating plant may serve as many as half a dozen wells.

The piping leading down into each well is made up of several pipes, ranging from one inch to ten inches in diameter, placed one within the other. The outermost pipes carry water down to the sulphur-bearing strata, where it passes out of the piping through perforations. Within the water pipes, which are six and eight inches in diameter, is a 3-inch line extending to the bottom of the well. The sulphur, as it melts, flows to the bottom of the well and is raised through this line to the surface of the ground by means of compressed air fed through a 1-inch pipe within the 3-inch line. The wells are over 1,000 feet deep.

Letters From Readers

"Not Guilty"

To the Editor,
Canadian Mining Journal;

In a recent issue of the *Journal,* Mr. C. M. Campbell upbraided the daily press and technical journals of Canada for their silence with regard to the late J. D. MacKenzie's report on "Coal Resources of Southern Vancouver Island," which, according to Mr. Campbell, was issued by the Geological Survey on the first of June.

As Mr. Campbell's article was the first intimation I had received that the report had been published, I wrote at once to Ottawa for a copy, and, in reply, received a letter from Mr. Wyatt Malcolm, chief of the division of geological information, stating, among other things: "I am afraid the statement in the *Canadian Mining Journal* has led to some misunderstanding about the status of the report. It has not been published. We had a few copies mimeographed for persons very directly interested, (presumably the managers of the collieries on the island.) It will not be until the report is published that we will have a stock for general distribution."

Under these conditions it is hardly surprising that the press—technical and daily—has had nothing to say on the matter.

Victoria, B. C. F. H. Mason.

Mr. Campbell Discusses Induction and Deduction

To the Editor,
Canadian Mining Journal,

A natural action after reading Dr. Corless' letter on the above subject is to find out to what extent Dr. Corless' published statements agree with the rules he refers to.

The whole matter is summed up very briefly in the *Britannica* as follows: "Induction normally leads, not to a necessity, but to a *probable* conclusion; and whenever its *probable* conclusions become deductive premises the deduction only involves a *probable* conclusion.*" The italics are my own.

Let us now take Dr. Corless' conclusion that it is a "fact" that "we have inconceivable wealth in minerals." This was based on several premises consisting of so-called facts and inductions.

These premises need not be again discussed here. Even had Dr. Corless been right in his facts and even had his inductions been warranted, his conclusions would only have been a probability. In stating it as a "fact" he violated the rules of logic. The article from which I quote says that the degree of probability is variable and that at times conclusions rise to the point at which probability becomes moral certainty. The reverse however, is the case in this instance. Considering the grave errors in his premises, Dr. Corless' conclusion is nothing more than an extreme possibility and as such should never have been published.

The same authority** states that induction "is a scheme invented to meet a given situation, an hypothesis which is put to the test of events and is verified or refuted by practical success or failure." I venture to say that Dr. Miller when studying the relationship of the silver ore to the neighboring rocks discarded many inductions before he found one that stood up before every test. I venture to say, also, that Dr. Corless in trying out his deductions did not always have the good fortune indicated in the incident of the Garson mine.

I quite agree with Dr. Corless that an engineer should try to see beyond the ore he has blocked out; but before that engineer states a conclusion, in regard to local or national mineral reserves, as a "fact," it should be put to the test and verified; in other words the mineral should be actually blocked out.

Dr. Corless, I have said, believes that it is a "fact" that "we have inconceivable wealth in minerals." He then made the induction that every member of the Institute believed the same thing. Before going any further he should have put that induction to a thorough test. Instead, he made the same mistake as Richardson and Clapp on Vancouver Island. He jumped to the conclusion that his induction was a fact; that the measures were productive everywhere; or in other words that the members were unanimous; and therefore he signed the Institute's name to his claim. Here again he violated the rules.

I would like to ask Dr. Corless two questions. First, does he still believe that it is a "fact" that "we have inconceivable wealth in minerals?" Second, does he still believe he was justified in signing the Institute's name to a statement of that sort?

It is this habit of stating as a fact what is only a possibility that has got us into the mess we are now in. I have referred in a previous letter in this *Journal* to present conditions in British Columbia. A recent official statement says that the deficit on account of the Pacific Great Eastern alone now amounts to $3,000,000 per year. This road would not have been built if the public had not been hypnotized by such extravagant statements as Dr. Corless has issued in the name of the Institute. To pay this money we have to sacrifice many things that a community holds dear and many things that to touch would ordinarily be called sacrilege.

At the present time Vancouver is so badly in debt that to make her budget balance she has to curtail the education of her children. By-laws to improve fire protection are always defeated and, as a direct result, in the last few weeks lumber mills valued at $350,000 have burned down. Notwithstanding shortage of water in the summer, a large lumber concern is logging in the watershed from which she derives her water supply. Vancouver had, originally, one of the finest natural settings of any city in the world; yet, with the exception of Stanley Park, all the nearby roads have been denuded of their beautiful groves of trees.

On the strength of "inconceivable wealth" Victoria plunged with the rest, and that city is now notorious as having the largest per capita debt, even after allowance is made for utilities, of any city in the Dominon—and that is some record. On its outskirts are the Outer Wharves, a monumental piece of extravagance, built some years ago at a cost of about $5,000,000. Interest has nearly doubled that figure, and this interest we are all paying and shall continue to pay. Recently I stopped there. There was one boat in the harbor—the one I was on; the piles were rotten, the sheds were empty and the streets nearby were covered with grass. The wealth that was to make this a busy spot has not materialized. Notwithstanding hard times and the need of economy, the Federal Government, with the record of these wharves before it, has plunged again and voted more millions for the construction of a magnificent dry dock which is now being built.

Belief in inconceivable wealth of natural resources is the worst thing that has ever cursed this country and I shall denounce it, and the logic that makes Canadians believe in it, whenever I am given the opportunity.

Cassidy, B. C. C. M. Campbell

Mineral Resources along Hudson Bay Railway and round Hudson Bay

Summary of Information by Natural Resources Intelligence Service

The Natural Resources Intelligence Service, Ottawa, have lately prepared for distribution to those interested a 35 page mimeographed memorandum, with a blue print map, from which the following, relating to the mineral industry, is extracted. Its purpose is to give a brief synopsis of the important available information concerning the resources of that portion of the country lying adjacent to Hudson Bay, and the Hudson Bay Railway in particular. It has been compiled mainly from reports of exploratory parties and from data contained in federal and provincial Government publications. In a few instances information has been procured from unofficial sources and its accuracy cannot be guaranteed.

Physical Features

The district adjacent to the partially constructed Hudson Bay railway lies almost altogether in Manitoba and is roughly bounded on the southwest by the Pasquia hills, on the northeast by Hudson bay and on the southeast and northwest by the Hayes and Churchill rivers respectively. This represents an area about 160 miles wide and 450 miles long, some 70,000 square miles in extent.

The district is drained by three rivers flowing northeast to Hudson bay by parallel routes and traversing regions similar in type. The Nelson river is the central and largest of these, the other two being the Hayes and the Churchill, as previously mentioned. The Saskatchewan, another large stream indirectly feeding the Nelson via lake Winnipeg, flows east across the southern limits of the belt between the Pasquia hills and the Nelson height of land.

The whole region is in low relief, the hills being seldom more than 200 feet high and the central slopes being 400 and 500 feet above sea level. The highest point along the railway is Elevation 962', at a point 60 miles northeast of The Pas. Much of the country between the Nelson and the Churchill rivers is of very gentle gradient, both locally and as a whole. Geologically the district is arranged in three general belts crossing the rivers at right angles of which the middle and most widespread division is part of the great Laurentian plateau, here 250 miles wide (as measured along the railway) with Pre-Cambrian crystalline rocks deeply covered by clay soils. South of it is a tract about 60 miles in width lying on flat limestone formation (Ordovician) thinly covered or bare of soil and draining southward to the Saskatchewan river. The Saskatchewan valley is confined towards the south by a series of escarpments of which the Porcupine mountains, Pasquia and Wapawekka hills form the prominent features, and which constitute the northern boundary of the Great Plains regions in this vicinity. Between the Laurentian and the Ordovician are outcrops of Huronian and Keewatin rocks, which are a mineral bearing series. North of the Laurentian, for 125 miles inland from Hudson bay, is the third geological belt consisting also of limestone formations (Ordovician with overlap of Silurian) with a wet clay and gravel subsoil and surfaced with mosses and frozen bog. It is believed that much of this district sometimes known as the Arch-Hudsonian swamp, was previously occupied by sea waters which have now receded and are still receding slowly. The shores of Hudson bay on both sides of the Churchill are low and of such flatness that the tides cover them in places for several miles inland.

Hudson Bay

Hudson bay, into which the waters of these flow, is a great inland sea 900 miles north and south and 500 to 600 miles east and west extending deeply into Manitoba, Ontario and Quebec from the North. It is connected with the Arctic ocean by Fox channel and the Gulf of Bothnia and with the Atlantic Ocean by Hudson strait, a passage 500 miles long and from 45 to 100 miles wide, with deep water, few islands and pronounced shore lines furnishing good harbours on both sides. Due largely to the actions of the tides which in places are very high, 30 to 40 feet, and very strong, 6 to 7 miles per hour, the strait never freezes over but is the scene of many ice collections which come from down through Fox channel and to a lesser extent from Baffin's bay. he west shore south of Churchill and for 150 miles north is low, flat and without harbours; 200 miles north the coast becomes more rugged with inlets, harbours and islands. The east coast is irregular and bold with numerous islands and reefs. Pre-Cambrian rocks, largely granite and granite-gneisses, form both west and east coasts while the south shore from Churchill to James bay is made up of Palaeozoic limestones with Pre-Cambrian rocks further inland.

James bay, the southern extension, is 250 miles long, 120 miles wide and about 30,000 square miles in area. It is shallow for the most part, but deep water may be found well out from the west shore.

Many of the islands of Hudson bay are large and possess latent mineral and other resources.

Climate

Except for the summer months the climate of Northern Manitoba and adjacent districts of Ontario is several degrees colder than the northern agricultural belt of Saskatchewan and Alberta. Nevertheless it is by no means disagreeable. The daily hours of summer sunshine are long (about 18), and the low absolute altitude is favorable to early maturity of field crops. The winters are severe but exhilarating. Precipitation averages about 17 inches of which one-third falls as snow. The maximum distribution is in mid-year with a tendency for the wet season to extend through September.

Agriculture

Some settlement has been made in the Saskatchewan valley and along the routes of travel but it cannot be said that the agricultural future of the country has been accurately determined as yet, despite the fact that success has been met in a small way. At the same time prospects are by no means discouraging. The extent of arable soils is known to be considerable; rainfall is sufficient and well timed; and summer temperatures as recorded at The Pas and Norway House are

exceedingly favourable to fast growth and early maturity of field crops.

Water Powers

Enormous quantities of hydraulic power are within transmission distance of the railway belt, the Nelson river alone being capable of almost two and a half million horse power at ordinary minimum natural flow.

In connection with the proposed smelter at the Flin Flon mine it will be necessary to obtain power either from the Churchill, Saskatchewan or Sturgeon-Weir rivers. The Scoop Rapid site on the latter is most favoured.

Of the other rivers flowing into Hudson and James bays it may be generally stated that those draining from the west are of gradual descent in their lower reaches and possess few falls of consequence within economic transmission distance of tide water, while those coming from Quebec territory possess important power sites, many at or close to the coast. From present sources of information the Eastmain, Rupert Nottaway and Great Whale rivers are capable of furnishing about three quarters of a million horse power at ordinary minimum flow. Nastapoka falls, adjacent to the Nastapoka iron fields, has a descent of 170 feet and theWyachuan river has a fall near Richmond gulf of 315 feet and the Langland river one of 60 feet near its mouth.

Uses for this power have not been developed as yet, but three logical industries, all of which depend on cheap power in large quantities, suggest themselves - 1. Smelting of copper and iron ores in electric furnaces. 2. Production of fertilizers by fixation of atmospheric nitrogen. 3. Pulp and paper enterprises.

Minerals

The most outstanding mineralized area yet discovered in these parts is a belt 125 miles long and 20 to 40 miles wide extending east and west from Herb lake Manitoba, to Amisk lake, Saskatchewan, and crossing the Saskatchewan-Manitoba boundary just south of latitude 55 degrees. This is known as "The Pas Mineral Belt". The geology which characterizes it. Keewatin (including Huronian) formations between the limestone and Laurentian rocks (granites), is carried much further and has been traced in a general way east as far as God's lake, Hayes river, and west to Lac La Ronge, Churchill river. This is similar formation to the mineralized portions of Northern Ontario.

Gold and copper are the outstanding discoveries so far, and, while production was attempted for a while, lack of capital in the one case and falling markets in the other resulted in the closing up of active properties till such time as power and transportation could be obtained and metal prices had recovered. The existing active camps beginning at the interprovincial boundary and going east are:

1. Flin Flon and Schist Lake camp
2. Athapapuskow Lake camp
3. Elbow Lake camp
4. Herb (Wekusko) and Little Herb Lake camp.

The mineral formation as outlined by R. C. Wallace, Commissioner of Northern Manitoba in 1919, is made up of three classes grading into one another.

1. Gold in quartz veins carrying sulphide.
2. Copper-zinc-iron sulphide bodies.
3. Iron sulphide bodies.

Due chiefly to difficulties of transportation, the mineralized sections of the more general Hudson Bay district have received very little attention. Doubtless with rail communication with Port Nelson, Churchill or one of the James Bay ports much additional prospecting and development work will ensue. Of the islands to the north only a cursory examination of limited and coastal regions has as yet been attempted, although coal, iron, copper, gold, silver, lead and other minerals have been reported by explorers.

The following references summarize briefly the various native minerals of the railway belt and Hudson Bay coasts and their reported occurrences:

Antimony

Stibnite (antimony sulphide) is associated with the galena deposits north of Little Herb river, but to no great extent.

Anthraxolite

A bituminous mineral with the lustre and colour of anthracite is found in irregular veins or globules on Long island. It is not of economic value due to the small size of the occurrence and the high silica ash residue on burning.

Amber

This fossil resin is thrown up by waves on the shores of Cedar Lake just south of the entrance of the Saskatchewan river in small broken pieces the size of beans. The amber is believed to be derived from the Tertiary or Cretaceous lignites occurring on the Saskatchewan. Its use as a filler in the manufacture of varnish has been suggested, but the present supply appears too uncertain and inadequate for any commercial development.

Arsenic

Arsenical pyrites (mispickel) is present in a diabase sill on an island in the Nelson river in the Pipeston Lake area, also on some of the Wekusko lake properties and south of Corbett inlet, Hudson bay.

Asbestos

Small veins of asbestos are known to occur south of the Little Whale river, on the Ottawa islands, Hudson Bay and on an island in Lac LaRonge, Churchill river. J. B. Tyrell reports a deposit of possible value on Cross lake, Nelson river, on the Indian Reserve island, while another discovery is alleged to have been made near Amisk lake, Saskatchewan.

Building and Ornamental Stone

Large quantities of magnesian limestones for quarrying are exposed close to the railway in the vicinity of Cormorant, Reed and Atikameg lakes. This stone could be taken out in blocks 1 - 5 feet thick and in all sizes and would prove an excellent stone for structural purposes. The granites on the Grass river below Reed lake are well coloured and seem of a type suitable for dressing and polishing. This stone can also be obtained near Grand Rapids. Black marble suitable for quarrying has been reported by propectors working northeast of Amisk lake. Building materials of fair quality is found at Churchill. A variety of building stones are found on the islands and mainland of Hudson Bay betwen the Great Whale and Nastapoka rivers. On Walrus island of the Paint Hill group is found a porphyry rock holding pearly crystals of feldspar set in a dark green ground mass. Large slabs of this rock could be obtained for interior or exterior decorative uses. Agates, carnelians, epidosites and porphyries suitable for polishing can be obtained between Manitounuck and Nastapoka Sounds.

Clay

Clay suitable for brick manufacture occurs over a wide area, from Setting lake to Armstrong lake (100 miles), in the valley of the Limestone river, in local depressions in the boulder clay, and just north of Manitou rapids, Nelson river. The more calcareous clays are to the south. All are free from pebbles and could be burned to commercial hardness at 1,800 degrees. F.

Cement and Lime

The magnesian limestones which extend across the railway belt just north of the Saskatchewan river are suitable for burning for lime, while the upper portion of the series of the highly calcareous bituminous shales underlying the Pasquia hills can be used in the manufacture of cement. The pure dolomites of the Manitounuck islands would make excellent lime and cement materials, while a possible hydraulic cement stone is said to occur on Belanger, White Bear and the Nastapoka islands.

Coal

A sample of lignite received by the Mines Department, Ottawa, in 1907, described as from "an unsurveyed area northwest of Cumberland lake, Saskatchewan", showed the following analysis: moisture 13.25%, volatile combustibles 28.97%, fixed carbon 24.80%, and ash (including sand) 23.00%. This was probably a continuation of the lignite deposits of Lac La Ronge and Wapawekka lake, Churchill river. Lignite is also found on some of the Ontario rivers reaching James bay. Discoveries of lignite in the Pasquia hills have been reported but not verified. Stefansson, the Arctic explorer, says that he has seen coal in nearly every island north of Canada.

Cobalt

Cobalt has been seen in the form of fine-grained smaltite and cobalt bloom east of Big Island lake, and occurrences are also noted in calcite veins on the Belcher islands but not in economic quantities.

Copper

Copper sulphides of large extent and varying richness occur in The Pas Mineral Belt between the Saskatchewan-Manitoba boundary and the Grass river.

From the Mandy mine, Schist lake, 26,000 tons of ore have been mined and transported by waggon, barge and railway to Trail, B. C. for treatment. This ore contained 19½% copper with gold and silver values. 180,000 tons are now blocked out, the estimated content being 6% copper, 20% zinc and values in gold and silver.

The Flin Flon mine is the largest known commercial ore body in the province, 16,000,000 tons having been blocked out by diamond drills, shafts and drifting with the following estimated average values: gold .081 oz. per ton, silver 1.17 oz. per ton, copper 1.88%, zinc 3.80%. As will be seen this is a low grade deposit and will have to be handled in a large way with a small margin of profit per ton. Development involves building of an 85 mile, $2,500,000 (estimated) railway from The Pas to the property, harnessing of 10,000 hydraulic h.p. on Sturgeon-Weir river or Churchill river and the construction of a light railway from Flin Flon lake to the power house, the erection of a smelter on the property of 2,000 tons daily capacity and the establishment of a townsite for a population of 3,000 to 5,000. Fluxes could be obtained within about 15 miles or so, while the nearest suitable coal would be in Alberta.

Electric smelting, a new metallurgical practice for the treatment of copper ores, has been considered in connection with the Flin Flon owing to the high fuel costs, enormous water powers being within transmission distances of the mines. The Bureau of Mines of the United States made experiments along these lines, though not on an industrial basis, which tended to show that with the cost of electrical energy at $16 per Kw. year and coke at $9 per ton the cost of the two processes would be about the same.

Other occurrences are at the mouth of the Pineroot river, at Thompson and Twin lakes, all near Athapapuskow lake, at Pipestone lake, East river, between lake Winnipeg and the Nelson. Some development work has also been done at Elbow, Copper and Little Herb lakes.

There are Huronian rocks on the main land of Hudson bay at Cape Fullerton north of Chesterfield inlet containing 4% copper pyrites, and chance specimens showing small quantities of nickel and copper have been picked up northward of Portland promontory in the vicinity of Mosquito bay with promising indications of sulphide ores in the form of pyrite, pyrrhotite and chalcopyrite.

Iron and copper pyrites are reported at various points on the east side of Hudson bay and chalcopyrite, occurring in metamorphosed limestone, has been noticed on the Belcher islands but not in economic quantities, and in the vicinity of Lac La Ronge, Saskatchewan.

Flux Material

Limestone suitable for flux can be obtained in quantities from the lake Winnipegosis region and could be delivered by barge to The Pas from a point a few miles from lake Winnipegosis via Cedar lake and the Saskatchewan river. The question as to where this material can be got to best advantage for the Flin Flon enterprise, is not as yet definitely settled.

Silica can be obtained from the numerous quartz veins in the mineral belt, most of which carry gold values. This gold would be recovered in the metallurgical treatment of low grade copper ores such as the Flin Flon mine possesses.

It is estimated that if the owners of the Flin Flon property built a 2,000-ton mill, a daily charge of over 320 tons of quartz and 660 tons of limestone would be necessary.

(To be continued)

Electric Lamps

The General Electric Company investigated the properties of Tungsten, and, by the use of a few hundred pounds for electric lamps, a saving of $250,000,000 annually is made in the United States alone.

Aluminium

Aluminium was discovered by a German chemist, and originally cost $90 a pound, but at this price its discovery was of little value to the public. It is now manufactured at Niagara and Shawinigan Falls, and the scientific work done by Hall and Heroult has reduced the cost to 22 cents.

PERSONAL AND GENERAL

Sir Alfred Mond is to inspect the Mond Nickel Company's mines and smelter in the Sudbury district before returning to England.

Dr. J. Austin Bancroft has returned to McGill University from British Columbia, where he spent the summer examining mining properties in the vicinity of Anyox on behalf of the Granby company. Most of his time was devoted to the Maple Bay properties, of whose future he is very hopeful.

Capt. George Black, M. P. for the Yukon, left Dawson on the last boat of the season. The summer has been exceptionally long, and fine crops of vegetables and hay have resulted.

Mr. E. W. Beatty has announced that two large, new vessels will be added to the British Columbia Pacific coastal fleet of the Canadian Pacific Railway. The rapid growth of the mining industry along the coast, as well as the attractions of the coastal trip to tourists, has crowded the present fleet with traffic.

Mr. Louis P. Collin has been appointed ceramic engineer at the Mines Branch, Department of Mines, Ottawa. Mr. Collin is a graduate in ceramics of Alfred University, which has one of the principal ceramic schools in the United States. He has had a thorough practical experience in various lines of ceramic work, and at present is in southwestern Ontario studying some difficulties of brick manufacturers.

Dr. B. R. MacKay has been appointed geologist on the Geological Survey, Ottawa, to work on coal in collaboration with Dr. Dowling, Canada's veteran coal specialist. Dr. MacKay recently concluded an engagement with an English petroleum company in India, and was successful in locating a prospective oil field as a result of a refined study in sedimentation. A large appropriation has been made to test this field.

Dr. T. L. Tanton has returned to Ottawa on completing his season's field work in Thunder Bay district, where he made a detailed geological map on a contoured base of the old silver area. The Loon Lake iron ore deposits, which are in this vicinity, have been diamond-drilled during the past summer by the M. A. Hanna Company who operate mines, also in the Animikie series, on the Gogebic range in Minnesota. Dr. Tanton was accorded the privilege of examining the diamond-drill cores in Duluth, and also examined the M. A. Hanna mines on the Gogebic range, immediately following his examination of the Canadian deposits in the Animikie.

Dr. W. E. Cockfield has finished his field work for the year in the Yukon. He reports a successful mining season at Keno Hill, while all indications point to an even more successful year during 1924. During the summer he made a brief examination of some new silver-lead deposits on Beaver River, a tributary of the Stewart, 50 miles north of Keno Hill. This ore he found to be of comparatively low grade, and hence of no immediate commercial value. It is very interesting, however, as indicating the wide area over which this silver-lead ore occurs.

During the past summer Dr. D. B. Dowling has made an examination of the coal measures in the Bow River valley, south of Canmore, B. C., with a view to locating coal that would be completely suitable for shipment to Ontario as household fuel. The coal of the Bow River valley is much like Welsh anthracite, with fixed carbon from 75 per cent. as at Canmore, up to 80 or 82 per cent. as at Bankhead, and only two or three per cent. of ash. It breaks up, however, on exposure to the weather, due to intense folding of the coal seams. The area Dr. Dowling examined last summer has not been thus folded, and if the analyses of samples should show the quality to be first-rate, as it is elsewhere in the vicinity, it is quite possible that it will provide the best coal in the West for shipment to Ontario.

Messrs. James J. Hill and H. G. Pickard of the Haileybury High School are doing good work for the mineral industry, as is shown by a recent encounter in the woods. A well-known geologist ran across a young prospector in the gold belt of northern Quebec, and found him remarkably well equipped with the scientific lore of his calling, and most adept in applying it in practice. After a few days it developed that this young man was a graduate of the Haileybury High School in mining.

Dr. George Hanson, accompanied by H. C. Gunning and R. H. B. Jones, of the Geological Survey of Canada, have left Stewart, B. C. for the south after having completed a season's survey work in the Salmon River section of the Portland Canal district.

Mr. F. D. A. Vincent, of the firm of Vincent & Co., London, who is heavily interested in the B. C. Silver Mines Ld., whose property adjoins that of the Premier Gold Mining Co., recently visited the Portland Canal mining camp and made a personal inspection of the property in which he and his associates have invested.

Mr. D. J. Williams, manager of the Hirst Chicagof Mine, Alaska, has been inspecting a number of prospects in the Portland Canal district.

SOUTH AFRICA'S GOLD ORE RESERVES

In a recent number of the *South African Railways and Harbours Magazine*, Mr. H. C. Hopkins observes as follows:

Gold mining is said to have reached its zenith in South Africa. This, in Mr. Hopkins' opinion, is still a debatable point, and is dependent apparently upon the maintenance of working costs within economic limits. Continuous research work produces new ideas, and with constantly improved and cheapened methods of extraction it seems probable that huge quantities of ore of low gold content, now untouched, may be brought within the limits of payability. Improved and cheapened methods of treatment will also attract capital for the development of other known large gold fields which are still unproclaimed and unworked. The Government Mining Engineer has estimated that there are still available 440 million tons of ore which will yield between 3 and 4 1-2 dwt. of gold per ton, in addition to 340 million tons carrying 4 1-2 dwt. and over.

It may be that manufacturers overseas have been deterred from investigating the potentialities of South Africa through a fear of the decline of gold mining; but let them ponder well the foregoing, and if they will also consider the progressive activities in other forms of mining—coal, iron, copper, tin, silver, mica, asbestos, corundum, lead, zinc, talc, manganese, nickel and oil shale—it will be apparent that long before gold mining has become exhausted other forms of mining may have filled its place. Yet further possibilities exist in osmiridium, platinum, vanadium, molybdenum and other rare metals which only await enterprising exploitation.

Selenium has been shown to be useful to vulcanize rubber, in place of sulphur, or admixed with it.

VALUABLE DATA FROM EXPERIMENTAL BLAST-FURNACE

The study of the reduction of iron ore in the blast furnace, that has been in progress for four years under the direction of the United States Bureau of Mines, at Minneapolis, and which has resulted in the successful development of an experimental blast-furnace by the bureau's metallurgists, has yielded data that may lead to important modifications in the present design of blast-furnaces. The Bureau of Mines engineers are able to make iron successfully in a small furnace stack only 20 feet high, and the tests show that a considerable part of the stack is inactive, so far as the reducing effect of the furnace gases on the ore is concerned, between the combustion zone and the zone near the top where reducion is actively going on. Since nothing happens in this part of the stack, if the same conditions hold true in commercial blast furnaces the present tall stack universally employed could be shortened, thus reducing cost of construction, and size and cost of equipment such as the blowing engines that drive the furnace. Further work is being pushed vigorously with the object of tying up the experimental results with those obtained in commercial furnaces.

This furnace, the only one of its kind in the world, had been regarded as impracticable by many leading iron metallurgists. It has a hearth diameter of 20 inches and a height of about 20 feet, and two successful runs have been completed with every operating detail under perfect technical control. With this furnace, which can be operated at comparatively small expense, the Bureau of Mines is now in a position to make a scientific study of the blast furnace process and to attack various problems, the solution of which should be of value to the industry.

Since the furnace is operated for obtaining information, special provisions have been made for taking observations. Openings introduced at five levels up the side of the furnace were provided so that the gas samples, samples of solid stock, and temperature and pressure observations could be taken as a means of determining the more important chemical and physical reactions occurring within the charge column. Work of this character is a continuation of the efforts of Ebelmen, Bunsen, Bell and other earlier investigators, to obtain data on the changes that occur in the smelting of iron ore as the descending materials, charged in the top, encounter the ascending stream of gas from the combustion or tuyere zone of the furnace. The blast-furnace process is known to consist of a series of inter-dependent reactions, and information concerning only the materials charged, the gas given off, and the products tapped from the furnace, is inconclusive. In order to make an effective study involving as many variables as are contained in the blast-furnace process, it is necessary that the investigators be able to change the independent variables at will without regard to commercial considerations. This can only be accomplished by means of an experimental furnace operated solely to obtain information.

With a furnace whose operation can be controlled and which will make pig iron, ferromanganese, and spiegeleisen, the Bureau of Mines is now in position to undertake a study of special problems. In co-operation with the University of Minnesota, a new furnace, designed by the bureau, will be constructed in the new Mines Experiment station now ready for occupancy. The problem of utilizing the low-grade manganese ores of the Cuyuna Range will be undertaken as soon as this furnace is completed. Facilities for handling materials, as well as for sizing, crushing and sintering them, are now available. It is believed that this study will eventually lead to useful information regarding:

(a) Utilization of non merchantable manganiferous iron ores,

(b) Furnace design from a metallurgical viewpoint,

(c) Fundamental data on the blast-furnace process,

(d) Combustibility of coke.

IRON FORMATION OF LAKE ST. JOSEPH

The Ontario Department of Mines has now issued Vol. 31, Part 8, 1922, a forty-page report by Dr. E. L. Bruce on the iron formation of Lake St. Joseph, on the border of Kenora, Thunder Bay and Patricia districts. It is accompanied by two geological maps of parts of Lake St. Joseph, that showing the iron formation being on a scale of one mile to the inch, while the second, to the east, is two miles to the inch. Dr. Bruce viewed the area from an air-plane of the Air Board at the end of the season (1921) and described this experience in a paper before the Canadian Institute of Mining and Metallurgy in March, 1922.

The rocks of the region consist, in general, of Keewatin rocks of both sedimentary and volcanic origin, intruded by granitic rocks. Iron-bearing beds occur near the upper part of the sedimentary group of Keewatin rocks. The outcrops of iron formation are extensive, but the content of iron is relatively low. Some of the higher-grade portions run 32 to 38 per cent. iron, with silica as the principal gangue material. There is little possibility of any enrichment in these beds, as in the Lake Superior field, as there have been fundamental differences in the life-history of the two cases. The beds in Ontario were covered up soon after their deposition, thus preventing the surface alteration that produced the ore-deposits of Minnesota and Wisconsin.

RECOVERY OF METALS FROM SLAG BY FLOTATION

An unusually suggestive statement by Dr. C. W. Drury of Queen's University, Kingston, relative to some research work he has conducted appears in the October issue of *Mining and Metallurgy*. Dr. Drury says:

"There is no question that attention will be devoted within the next few years to the recovery of metals from slag. Increased mining and smelting costs, along with lower metallic content of ores, will hasten the time when materials now considered as waste products will be regarded as a source of metal.

"The most suitable method of recovering metals from slags will do, no doubt, vary according to conditions and the value of the metal. In the course of some experimental work in this connection, the writer has made a number of tests. The slag consisted essentially of silicates of iron, lime, nickel, cobalt, and copper. In the tests the object was, first, to add the requisite and proper reducing agent which would reduce the nickel, cobalt and copper to metallic form. The reduced metal would not melt at the temperature of the molten slag. To recover and collect the reduced metallic particles, carbonate of lime or soda was added, with the result that a spongy mass came to the surface and was readily removed. Under certain conditions it was necessary to add basic material to the slag. In several tests a recovery approaching 90 per cent. of the nickel, cobalt and copper was obtained."

REPORT ON MINE TIMBER

The kinds of timber used in mining operations are as varied as the localities in which the mines occur, states the United States Bureau of Mines in Bulletin 215, just issued, as a result of a study of the timbering of metal mines just completed by the Bureau of Mines. In some districts in which there is a scarcity of good timber, such as in the Southwest, the prospector and small mine operator use the dwarf varieties usually found in these arid regions, such as mesquite, sage brush, juniper, cottonwood, pinon, etc.

Long-grained timbers such as pine, fir, spruce, oak, and chestnut are preferred because they will crack and split when pressure comes on them, and thus give warning long before they break. Although timbers should be long-grained, strong, and elastic, they should not be too heavy. Oak and chestnut and other long-grained hard woods are strong, but many hardwoods are heavy to handle. Short-grained woods are often unreliable as an indicator of dangerous pressure because they may break without warning.

The Bureau of Mines advises that the use of such flexible woods as hickory, eucalyptus, and willow be avoided, if possible, as they bend easily under pressure and do not offer, in proportion to their size, much resistance to the movement of the rock. The willow especially lacks both strength and durability.

Those timbers of the Pacific coast that are best adapted to mining uses are Douglas fir, California fir (white fir), Sitka and white spruce, and yellow pine (bull pine), but western hemlock, cedar, and redwood, also oak, maple, chestnut, and other hard woods are used where most easily available. Sometimes the scorched timbers of burned-over districts are used. When the heart of the timber is sound these have proved acceptable; they are cheaper than unscorched timber and are practically as strong.

In Alaska there have been many objections given to the use of native spruce and native hemlock for mine timber. Some mining companies have preferred to ship in Douglas fir from Washington and Oregon instead of using the native woods. At present the amount of Alaskan timber being used in the miines there are much larger than formerly. Experiments by the Forest Products Laboratory on Sitka spruce and Alaska hemlock indicate that the better grades of these woods compare favorably with lodge-pole pine and Douglas fir.

A fundamental principle to be kept in mind is that mine timbering should afford adequate support at least expense. Enough timber should be used to insure safety to the workings and to the men, but as timbering is often one of the chief items of cost in mining, the excessive use of timber an economic waste.

Timbering serves primarily, by the prevention of caving and spalling, to keep the workings open for such time as is necessary for extracting the ore, or for purposes of transportation and ventilation. When the workings are abandoned, the timber therein has fulfilled its purpose and is so much waste material, although some of it may perhaps be recovered for re-use in other parts of the mine.

Because timber suitable for use in mines is becoming increasingly scarcer in nearly all mining districts, and at many places must be shipped in, and because of the labor cost involved and the further fact that most mine timber can not be recovered, there is greater and greater need for exercising good judgment in utilizing timber to the best advantage.

The most important principle of mine timbering is to timber in time; that is, immediately after excavation and before the rock inside the natural rock arch becomes broken and begins to settle. If this principle is followed it will save time, money, and many lives.

The ventilation of a mine has considerable effect on the life of the timber. Damp stagnant air will cause mold and fungus growth which will be followed by decay or rot. All timbered active places in mines should be well ventilated, and special provision should be made for the removal of the damp, hot air which is commonly found underground in pumping stations and around steam lines.

Timbers used in mines are subject to destruction from decay and insect attack, breakage, mechanical wear and fire. It is estimated that under average conditions 50 per cent of the total timber used is destroyed by decay and insect attack. Decay and its accompanying evil, boring by insects, the most destructive agencies acting on underground timber, can be retarded by peeling and seasoning the timbers before use, and by treatment with a suitable preservative. While it may not always be feasible for the small mine operator to use preservatives, peeling and seasoning timbers is always possible. Bark, when left on the timber, retards the evaporation of moisture, leaving the timber more easily attacked by fungus growths and various wood-boring insects.

The average life of green, unpeeled, and untreated timber used in a mine is from one to three years; but by peeling alone, the life of timber when used in dry mine workings may be increased 10 to 15 per cent. There are several kinds of wood preservatives which have been used successfully on mine timbers—creosote, zinc chloride and sodium flouride are the ones most commonly used. The bark should always be removed from the timbers before treatment.

THE SUPERIORITY OF BRITISH CHINA CLAY

Foreign Deposits Reviewed

Dependent as the rest of the world has been upon the unlimited supplies of English china clays from Cornwall, it is, we suppose, only natural that other countries should seek to find, within their own borders, clays approximating in quality and chemical constituents to those they have been in the habit of importing. With rare exceptions foreign exploiters have failed to find anywhere else in the world any kaolins to equal the quality of the best English china clays, but they have succeeded in developing some clay deposits that are at least equal to the common china clays of the West of England.

In no countries are the efforts to find substitutes for our English clays so determined as in America and Canada. There is a lesson in this activity for English china clay producers, and it is for them to get busy to keep their "end up" across the water, where the maintenance of markets is of vital concern to the industry.

This can only be done, as has been frequently pointed out, by means of propaganda at least equal in energy and originality to that being undertaken by our friends across the water.

It is a matter of common knowledge that for some time past Americans users of this invaluable product have lately combined with a view of discovering other sources of supply. Up to the present it is a fact that only a relatively few deposits of good china clay of any commercial value have been found in the U.S.A., these chiefly being in the Southern States; but there

are, we believe, other important deposits being worked in Nevada, Colorado, California and elsewhere in America, but of much inferior quality to the British clay. It is now being pressed upon the Federal Government that a systematic geological survey should be undertaken with the view of ascertaining how far the U.S.A. can be made independent of imported supplies, and thus be in a position at least to compete with English china clays.

The Department of Mining recently despatched a special Trade Commissioner to China to investigate the subject, and the gentleman in question, Mr. J. Morgan Clements, has since reported that supplies of high-grade kaolin could possibly be obtained from that Republic after systematic exploitation. He particularly mentions the province of Fukien, which is more favourably situated to supply markets than those at Kiangshi, on the Yangtze, and at Shekwan, near Canton. Mr. Clements also directs the attention of the Department to the promising deposits which have been located, and are to-day being worked, at Foochow, near the South Manchuria Railway, the exports from which centre amount to something like 70,000 tons yearly. This, we may incidentally remark, is virtually the total quantity of china clay now being produced in Cornwall in one month. To assist in the development of this industry, it is proposed to link Foochow with the main line by a narrow gauge railway, an alternative plan being to connect the quarries with the coast, which is only about a mile distant. An additional promising field, producing high-grade clay in fair quantities, is situated close to Tumenling station on the Kirin Changchun Railway, the possibilities of which, we learn, are now being investigated. In all probability American capital and enterprise will be employed in the exploitation and development of these sources of supply.

Canada is at last likewise bestirring itself in a more systematic investigation of its china clay deposits, mainly with the view of developing its pottery industry. Up to the present, the only white clay discovered in the Dominion is at St. Remy D'Amherst, near Huberdeau, Quebec, 85 miles from Montreal. A number of unsuccessful attempts have been made to it, and a considerable amount of good clay produced. Other inferior clays suitable for the manufacture of pottery occur in Southern Saskatchewan. The D'Amherst deposit is about 1,000 feet wide, and is known to extend North and South for a distance of 7,000 feet. Much of it is stained with iron, and is consequently only suitable for fire-clay, of which a large quantity could be produced. As regards the deposit of white kaolin, a typical analysis shows its contents to be: 47.50 per cent silica, 1.06 per cent. iron oxide, 36.98 per cent. alumina, 0.23 per cent. lime, magnesia (trace only), potash 0.19 per cent., soda 0.18 per cent., loss on ignition 14.10 per cent. = 100.24 per cent. It is of a pure white colour, and its iron content is declared by Dr. M. E. Wilson, of the Canadian Geological Survey, to be negligible.

The size of the deposit is such that it may ultimately provide, not only for the needs of Eastern Canada, but leave a margin for a substantial export trade. This particular clay is said to be competing favourably now with some of the Cornish clays.

With Canada and the U.S.A. concentrating on china clay development, not to mention other countries like Malaya, the time would seem to have come for the home producers of china clay to make a combined effort to emphasize the superiority of their product over the best of all other kaolins. At any rate, they have still got the advantage of unlimited supplies near the sea-board, to enable them to compete in the matter of transport. — *The Chemical Age.*

INDUSTRIAL ITEMS

The Sullivan Machinery Co., Michigan City, Indiana, makers of mine machinery, have opened their new plant in that city and have moved all machinery from the old Chicago plant at 2824 West Lake Street to the new location. The company was organized at Claremont, N. H., in 1869 and 23 years later was merged with the Diamond Prospecting Co., an Illinois corporation. In 1902 the M. C. Bullock Co., Chicago, was purchased and became the Western Manufacturing unit. The principal manufacturing plant is at Claremont, where about 1,500 men are employed. Among the Sullivan company's products are air compressors, undercutting machines, rock drills and prospecting machinery. The management remains unchanged with Frederick K. Copeland, Chicago, president.

The Mine & Smelter Supply Company announce the promotion of Mr. J. P. Bonardi to the position of Sales Manager, of their New York office, succeeding Mr. E. S. Tompkins, who resigned recently. For the past two years Mr. Bonardi has been manager of the Assay and Chemical Department of their Denver house. His good record there accounts for his transfer to New York. Mr. Bonardi is a Chemical and Metallurgical Engineer, a graduate of the University of New Hampshire and of the Colorado State School of Mines. After leaving the latter institution he was connected with the United States Bureau of Mines until joining the Mine & Smelter Supply Company. He has had broad practical experience as well as technical training.

Mining men will be interested to know that the Taylor-Wharton Iron & Steel Company, of High Bridge, New Jersey, makers of the well known "Tisco" manganese steel, are offering new and efficient service in repair parts through their Canadian agents. This concern was founded in 1742 and introduced manganese steel on this continent in 1893. Almost every kind of industry is using their machinery parts to-day. Their experience, both as to method of manufacture and design, is very wide and this experience is now available to Canadian users through Lamoureux-Kelly Limited, 285 Beaver Hall Hill, Montreal.

The Mond Nickel Company have purchased the minority stock previously held by Messrs. Charles T. Hennig and G. P. Bassett, Jr., and are now the sole owners of the American Nickel Corporation, Clearfield, Pennsylvania, manufacturers of pure malleable nickel. Messrs. Hennig and Bassett are no longer affiliated with the Company in any capacity.

HUGE CARVING ON MOUNTAINSIDE

A carved war memorial, 1,100 feet long and 200 feet high, standing ten feet in relief, is described in the current issue of *Compressed Air Magazine*. It is now being cut in the solid granite rock of Stone Mountain in Georgia, U. S. A., as a memorial to the Confederate forces of the Civil War. The face of the mountain at this point is a sheer precipice of almost 1,000 feet, and the carving is being done on the upper part of this face. It is being executed by the sculptor, Gutzon Borglum, with the help of a large staff and pneumatic tools.

SOME REWARDS IN THE OIL INDUSTRY

The oil industry owes its popularity in the financial world to the fact that, although it contains a very large proportion of blanks, it also includes some exceptionally handsome prizes. The knowledge that occasionally a comparatively poor man may go to sleep at night and wake up a millionaire in the morning through a rich oil strike, appeals to the gambling spirit in mankind, which no amount of condemnation is likely to eradicate.

Only recently attention has been focussed on the very large stock dividends declared by some of the leading petroleum companies. These include a recent stock dividend of 400 per cent. by the Standard Oil Company of New Jersey; and the Vacuum Oil and Ohio Oil Companies, both subsidiaries of the Standard, have each paid 300 per cent. stock dividends. The Standard of New York has also declared a 200 per cent. stock dividend, and the California and Kentucky Companies have declared smaller but substantial dividends in stock. Several others are expected to follow these examples.

In 1913 the Standard of Indiana paid a stock dividend of 2,907 per cent.

It is said that these dividends are not due to economies, but that they are merely indications of the stream of wealth that may come from successful oil exploitation.

The following examples of cash dividends are also of an alluring character. The Royal Dutch, which is the nearest rival to the Standard Oil, paid 31 per cent. in 1921 and 26 1-2 per cent. in 1922. The Shell Company, a subsidiary of the Royal Shell, paid 27 1-2 per cent. in 1921 and 22 1-2 per cent. in 1922, and prior to 1921 had paid 35 per cent. for eight successive years. The Mexican Eagle paid 30 per cent. in 1922 on both ordinary and preference shares; and the Lobitos Oilfields, 25 per cent., with a bonus of 15 per cent. free of income tax for the year 1922, besides placing large sums to reserve and carrying forward a large balance.

These results represent those of the most successful companies, and are partly due to good fortune and partly to the foresight displayed by those responsible for the management and operation of the respective enterprises. Incidentally, much of the success has been due to the geological assistance rendered, obtained by a wise expenditure in engaging the best advice available.

The old adage that "nothing succeeds like success" is particularly true of the oil industry. It has often been pointed out that only successful companies can secure the highest skill, adopt the latest improvements in equipment, and endow research.

While shareholders in the above successful companies are to be congratulated on their good fortune, it must not be overlooked that the oil industry in the past has been mainly dependent upon itself for financial support. It is only in recent years that an oil proposition has come to be regarded as something better than a mere gamble.

Formerly oil enterprises requiring capital for extension could not readily obtain this from bankers or financial groups, and, therefore, were obliged to extend their operations out of revenue, which meant that dividends were either curtailed or entirely absorbed by the capital requirements. The large stock dividends of which so much has been made are in many cases the compensation for former sacrifices, in other words deferred dividends, and are not the result of unduly exploiting the petroleum-consuming public, as some have tried to show.

The above-quoted examples represent the rosy aspect of oil winning. The reverse side of the picture shows scores of highly capitalized oil undertakings which have lost all in pioneer exploration in various parts of the world, and the "wild-catters" who have never made good are to be numbered by the thousand.

It has been said of gold mining that it is carried out at a loss on the average—that more money is spent on prospecting and development than is, on the whole, extracted from the ground in the shape of gold. Nevertheless, the Californian goldfields, those of Cripple Creek, Kalgurli, the Witwatersrand, and the more recently discovered Ontario goldfields contain examples of mines which have yielded phenomenally large profits. It is probably much the same in the oil industry, and it is doubtful on which side of the profit and loss account the balance woulld appear, if it were possible to obtain the necessary data. Success advertises itself, but failure is of a more retiring nature, and rarely attracts attention unless it be of extraordinary magnitude or following a previous great success.

The oil industry, like most others, would gain by greater stability, and it is certanly a sign of the times that increased knowledge is tending more and more to eliminate the purely speculative element.

At the same time great prizes are still to be won in oil exploitation, and it is well that the certainty exists to give a zest to enterprise. What better knowledge can do is to reduce the number of failures, and to convince the speculator that there are cases in which nothing short of a miracle can give him a profitable result.—*The Petroleum Times.*

DOMINION FUEL BOARD RECOMMENDS COKING PLANTS FOR DOMESTIC FUEL

The central part of Canada is feeling the need at the present time of an ample supply of domestic fuel of a high quality at a reasonable price. The great strike of last year in the anthracite field was the cause of the acute shortage last winter; but the attention thus drawn to the subject has shown that the deposits of anthracite coal are limited and that the supply is being used up with comparative rapidity.

To assist in the obtaining and distribution of fuel of some kind to tide over this strike period, fuel committees, federal, provincial, and municipal, were created. These committees functioned through the winter of 1922-23 and are still in operation, but they do not touch on the larger problem, that of obtaining a suitable domestic fuel to take the place of anthracite. It was to deal with this problem that the Dominion Fuel Board was established by Hon. Charles Stewart, Minister of Mines. The function of this board is not to find fuel for a few months during an emergency, but to carry on investigations that may indicate to citizens a permanent source of supply. Their task, therefore, is a large one which will take time for completion.

Various lines of investigation are being followed, among others that of the commercial feasibility of producing coke in by-product recovery ovens in our larger cities. The field work in this investigation is practically finished and the information collected is now being prepared for publication. While the details are not yet available, it may be stated that conditions are found to indicate that the erection of plants at several points would be a warranted commercial venture for individual firms or corporations. Investigations are also being carried out by the board in conjunction with the Mines Branch to determine the coking qualities of Nova Scotia and New Brunswick coals and it is hoped these may be available for this purpose and thus relieve the supplies drawn from abroad.—*Mines & Resources.*

THE MINING DISTRICTS

By THE JOURNAL'S CORRESPONDENTS

NORTHERN ONTARIO

Kirkland. — Although it may be merely a coincidence that discoveries of very rich ore are being made in the Tough-Oakes so shortly following the listing of the stock, there is no question but that the recent underground developments have been much more favorable than formerly, and that some exceedingly good ore is being found. It has been decided to continue the main shaft from 800 to 1,100 feet. It is hoped that the company will soon be in a position to resume milling. The new company takes over all the interests of the Tough-Oakes, Burnside and Kirkland Lake Proprietary, and the board consists of four Canadian and three English directors.

Diamond-drilling is being done from the underground workings of the Wright-Hargreaves and Sylvanite mines. The Sylvanite is controlled by interests associated with the Wright-Hargreaves. The rich ore recently opened up on the Tough-Oakes is near the Sylvanite boundary, which adds a considerable prospective value to the latter property.

When the new plant of the Harvey-Kirkland is installed, the shaft will be continued from 200 to 400 feet. Another shaft is to be started on No. 6 vein, several hundred feet distant from the main shaft.

During the month of August the Lake Shore treated 2,066 tons and recovered $43,161, an average of $20.88 a ton.

Porcupine. — It is understood that the Hollinger plans for the development of its power on the Abitibi River have been approved by the Government. With this question settled, activity in construction can be pushed to the utmost limit.

South Lorrain. — During the month of August the Lorrain Operating Company, a subsidiary of the Mining Corporation, produced 137,560 ounces of silver. The latter company is meeting with very good success in the development of its Trout Lake property, where the shaft has now reached a depth of 300 feet. Very encouraging values were found for about 200 feet, at which point the vein dipped out of the shaft. A station is being cut at 300 feet, and lateral work will shortly be started. The Mining Corporation is also operating in the Gillies Limit and has a shaft down about 25 feet. It is probable that this will be continued to a final depth of about 300 feet.

Mr. Hamilton B. Willis has purchased two claims adjoining the Maidens property in South Lorrain. The Maidens is being operated by Mr. Wills and associates, who are identified with the Keeley.

Options Dropped. — The Coniagas company has discontinued work on the properties in Tashota, which it had under option. McKinley-Darragh has also given up its option on the Paul property in Lorrain Township.

Kerr Lake Annual Report. — The annual report of the Kerr Lake shows a total revenue of $345,000 and expenses of $34,000, leaving net profits of $311,000. Dividends to the amount of $300,000 were paid, leaving a surplus for the year of $11,000, and a total profit and loss surplus of $1,239,000. No work was done on the Kerr Lake property in Cobalt during the year, and the company's property in Utah has been practically closed down. Revenue at the present time is being derived from the Rimu Gold Dredging Property in New Zealand, which is controlled by the Kerr Lake. Profits for the year 1923 showed a decrease of approximately $100,000 compared with the previous year, and this is due largely to the falling off in revenue from the silver property in Utah, which was forced to close following the action of the United States Treasury in declining to make further purchases of domestic silver at $1.00 an ounce.

Mikado in Liquidation. — The Mikado Gold Mines in the Lake of the Woods district has gone into voluntary liquidation. It is stated that this plan is necessary in order to clean up various matters and put the affairs of the company on a better basis. It is stated that promotion stock was being sold at lower prices than the company was asking for treasury stock and that the company found it impossible to sell treasury stock in competition with promotion stock and raise enough money to finance operations.

Gold Production in September. — During the month of September nine Ontario gold mines produced approximately $2,000,000 which is probably the greatest output in any one month during the history of gold mining in this Province. Production, in order of importance, came from Hollinger, Dome, McIntyre, Teck-Hughes, Wright-Hargreaves, Lake Shore, Kirkland Lake, Argonaut and Croesus. From the last property a small amount of high-grade gold ore was obtained by sorting. A total of 216,000 tons of ore was milled, with an average recovery of about $9.00 a ton. Over five thousand men were employed in the mines, and an additional large number in other enterprises which contribute directly to the operating of the mines. While the September output probably established a record in gold production for the province, it will not be long before this will be exceeded. The present mines can be expected to maintain their output, while Vipond and Night Hawk Peninsular will soon be producing. If favorable developments continue on the Tough-Oakes, that mill should also be put in commission, while the tonnage being treated at the Argonaut is to be increased.

Matachewan Stocks. — The recent action of the stock of the Matachewan General, which broke practically 50 per cent. almost over night, would seem to call for some explanation from the Standard Stock and Mining Exchange of Toronto, if that organization is to receive the confidence of the mining public. The Mining Exchange would render a service to the public if activities such as those of the Matachewan General were properly investigated. There is a good deal of publicity given to the activities in the Matachewan district, but these activities appear to be confined more to conversation than anything else. It

is unfortunate for the district that the principal properties should be dominated by a firm of mining brokers who seem to be more concerned with the sale and manipulation of stock than with the development of mines.

NORTHWESTERN ONTARIO

The activity shown in the various sections of the Schreiber gold mining area, gives splendid promise of an exceptionally busy field of development and production in the near future. A number of men prominent in the eastern part of Northern Ontario's gold and silver producing areas, have visited this field recently in search of investment for themselves or principals, and have made examinations of properties now under preliminary development, with a view to their purchase.

Prospecting, staking and recording is more active at present in this field than at any time in its history. At Big Duck Lake, Cook's Lake, Harkness claims and Victoria Cape, valuable finds have recently been made that are of an exceptionally interesting and promising character.

Schreiber. — Mr. Hanson, representing John Taylor & Sons, London, has just spent ten days in sampling and investigating the Schreiber Gold Mines, Ltd. property (formerly McKellar-Longworth) and was apparently impressed with his findings. For some time past the work on this property has consisted mainly in stripping and trenching and has resulted in showing up a total of nineteen veins. At present three shifts of miners are employed in putting down a two-compartment shaft on number eleven vein, situated 1,000 feet south of No. 1 tunnel, and are down 22 feet. The vein covers the entire width of the shaft, and carries high values over this width from the collar to its present depth.

A discovery of gold has just been made in a vein 30 inches wide, on the Harkness claims, just east of the Jackson Gold Mines, Ltd., about three miles east of Schreiber, close to the Canadian Pacific Railway. The vein is traceable over two claims, and is being stripped and trenched, showing visible gold wherever opened.

Cook's Lake. — Another find of gold has been made northeast of Cook's Lake, by prospector Matheson, recently of Kirkland Lake, in an 8-foot vein of sulphides and quartz, in schist formation. It is traceable for three-quarters of a mile. This area is being staked rapidly, many claims having been recorded within the past few weeks.

Victoria Cape. — William Longworth has re-discovered a vein varying from eighteen inches to 4 feet, traceable for three-quarters of a mile, located in greatly altered granite on the contact, at Victoria Cape, on the west shore of Jackfish Bay. The vein has been stripped for 800 feet, and has been carefully measured and channel sampled for this distance, carrying values varying from $2.50 to $30, averaging rather better than $10. This vein was originally discovered by the late Donald McKellar, in 1875, and was the first discovery of free gold on the north shore of Lake Superior. At that time Mr. McKellar did some preliminary work and sampling, resulting in returns varying from $2 to $27 per ton, but nothing was ever done with it until Mr. Longworth began operations this summer. Mr. Craig, manager, and Mr. Huston, consulting engineer for the Tonopah Mining Company, arrived on the property on the 6th instant, for the purpose of making an examination, with a view to purchase.

Big Duck Lake. — Horace Strong, representing the Mining Corporation of Canada, has completed an examination of the Beaver (McQuaig) and McKirdy properties at Big Duck Lake. This examination was followed by another sampling and investigation by Mr. Rice, representing the same company, and the latter is now in the East, together with Messrs. Harrison and Hibbert of Cobalt, who hold an option on these claims, negotiating with the Mining Corporation as a result of the above examinations, with a view to their purchase by the latter.

Prospecting and staking in the Big Duck Lake area has been active all summer, and some promising finds are being made.

Jackfish. — Frank Campbell, one of the original prospectors at the Dome Mine, Porcupine, has acquired ownership of the Ursa Major, originally located in 1896 by the Jackes interests of Toronto. The property is situated north of Jackfish station, on the Canadian Pacific Railway, close to the granite contact, in the eastern part of the Schreiber field. Mr. Campbell has had a gang of men employed for some time, engaged in stripping and trenching operations, and has planned to do 10,000 feet of diamond-drilling on this property in the near future.

W. R. Chapman is at Jackfish, looking over several properties in the interest of some people of Belleville, Ontario.

NOVA SCOTIA

Steel Works Committee Doing Well.—The B. E. S Co. General Works Committee is doing splendid work and is creating a very fine spirit among the workmen. One of the first matters discussed was the reinstating in their employment of the men who were laid off during the strike. This in itself shows that the Committee is made of the right metal, and is not afraid to tackle hard problems. It is not always an easy and sometimes a very unwise thing, to restore workmen to their positions before they have come to realize that they have not always acted in the best interests of themselves and the company they served. This action, however, shows that the Committee fully realizes that the spirit of force is after all, not the best and progress can only be made when all working men go forward together, united in a common cause. The wolf at the door of the neighbor, even although he has erred, is far too vivid and personal a feeling to the average workman not to provoke sympathy. The spirit displayed by the Committe is altruistic and is sure to win over their brothers. When the stage has been reached where any corporation stands ready to discuss discipline with their workmen, the relationship existing is better than that of master and servant; it is bordering closely on friendship. The action of the committee will test and try out the qualities of this virtue in the Steel Plant. There can be no greater test of any workman than to discuss the conduct of a brother workman, and to decide what should be done with him. In this case the Committee have to deal with only one side of the matter, and that is restoring

their fellow workmen to their positions. The more difficult question of dealing with workmen discharged for cause is sure to come up at times; but the magnanimous spirit displayed at the very beginning of their work will inspire a confidence and trust in the good sense and judgement of the General Works Committee, which will go far to pave the way for the unchallanged reception of future decisions.

ALBERTA

Regulations Well Received. — Opinion among coal dealers of the Province of Alberta appears to be agreed that the new sales regulations, which were outlined last week, will work out to the advantage of the trade. In some quarters it was thought that too strict an interpretation of the rules might hamper business, but generally the disposition was to wait and see. That one good result would be the elimination of the "snowbird" seemed to be the opinion of most of the regular operators and dealers. This term is applied to traders who bloom in the winter, are not particular as to the class of coal they handle, and fade away with the return of warm weather. The activity of this class of businessman, it is stated, has had a bad effect on the Alberta trade in the Province of Manitoba and it is very desirable that some curb should be placed on such damaging irresponsibility at a time when Alberta is attempting to form permanent trade connections in the Province of Ontario. Chas. W. Leonard, president of the Northern Alberta Coal Operators' Association; W. C. MacKay, of the Fraser-MacKay Collieries Ltd.; and E. B. Johnson, manager of the Marcus Coal Sales, Wholesale shippers, are quoted as being satisfied with the principle of the regulations. They believe that they will, have the effect of protecting the trade and will be generally beneficial if the cost of administration does not prove excessive.

Not Hopeful of Coal Shipments to Ontario. — Mr. E. W. Beatty, President of the C. P. R., when in Western Canada recently made an interesting statement relative to the effort being made to place coal produced in the Province of Alberta in the markets of the Province of Ontario. He said that if the whole of the domestic coal trade of Ontario were secured by Alberta Collieries, it would only increase the operating losses of the railways, if any such rate as $7 a ton for transportation were put into effect. The Canadian Pacific Railway has not been a party to the $7 experimental rate for the reason that it was recognized that the movement could be made only at heavy loss and that the competition of American anthracite and bituminous coal would prevent the permanent use of Alberta coal at eastern points, even though the latter could be used in the case of a coal shortage or any other abnormal situation.

Coal Shipment from Hudson's Hope. — Forty-six tons of semi-anthracite coal from measures situated in the Peace River country in the vicinity of Hudson's Hope have been delivered by scow to the Canadian Pacific Railway to be used as a test of its steaming qualities in the locomotives of the E. D. & B. C. Ry., a subsidiary of the C. P. R. running into the city of Edmonton. If it is a success, of which there is no question in the minds of the members of the coal company, it will mean the establishment of a new coal industry in northeastern British Columbia. Neil Gething, W. Gething, L. Gething, and Leslie Aylard, all of Hudson's Hope, are the promoters of the enterprise.

Order for Coal from Ontario. — The Province of Ontario is securing ten thousand tons of Alberta coal through the Government of the latter Province and the coal operators of the Edmonston district recently received their first order of seven cars. This has been placed through C. W. Leonard, president of the Northern Alberta Coal Operators' Association, and will be filled without delay.

Gas at Wainwright. — Drilling for oil is active in the Edmonton and Wainwright districts of the Province, the two companies so engaged being the Imperial Oil Ltd., and the British Petroleums. Heavy gas recently was struck by the latter company at a depth of 2,080 feet. The Imperial Oil are sinking a number of wells, one of which is reported to have passed through gas and to be down 1,900 feet. Residents of Edmonton are watching keenly these explorations, and the news of outbursts of gas has led to the filing of a number of petroleum claims in the Dominion Land Office.

BRITISH COLUMBIA

Stewart. — Diamond drilling on the property of Indian Mines Ltd., commenced on October 1st and the work proposed is expected to be completed in six weeks. G. D. B. Turner, who has taken an active part in this development, has laid out the exploration program for the next two months and, with its completion, the hope is that plans may be made to place the mine on a producing basis without further delay. It should be shipping in the course of the next six months or within a year at the outside, if hopes are realized. Some 3,200 feet of development work has been done, comprising tunnels, drifts, crosscuts, and raises. The mine is equipped with a 12″ x 10″ Ingersoll-Rand compressor, driven by a 60 h.p. Fairbanks-Morse semi-Diesel oil engine; and a Rix 9″ x 6″ high-speed air compressor, connected to an 18 h.p. gasoline engine. There is a large steel oil tank of 15,000 gallons capacity. The main haulage tunnels and drifts are equipped with all the necessary air lines, ventilating pipe where required, track, mine cars and air drills. The camp buildings include three bunk houses, cook house and dining room with ample accommodation for 30 men; office and assay building, and stables, all situated at mile thirteen, near the present end of the waggon road. The mine is connected with the Stewart dock by good waggon road up the Salmon river valley and thence by three miles of trail to the mine. The Provincial Government have commenced the construction of a high-level bridge across Cascade Creek with a view to extending the road to the mine. Transportation from the contemplated mill to the Stewart dock presents no insuperable problem as there will be no difficulty in the installation of an aerial tramway.

Rossland. — Another shipment of very rich ore is expected to be made shortly from the I. X. L. Mine, Rossland, by the eight leasers who are developing it. They are quoted as saying that they still are working in ore of high value. The two adjoining properties, the O. K. and Gold Drip, also are said to be promising. Eight men are employed on the former and a strike of importance is reported. A trial shipment has been made from the Gold Drip, which is being developed by M. E. Purcell of Rossland, for the owner, Mrs. D. I. McKinnon of Lincoln, Nebraska.

Kaslo. — The operation of the Cork Province Mine, according to a report from W. H. Burgess, secretary of the Company, is proving satisfactory. He states that good mill feed is being obtained containing 15 to 20 per cent. lead and 10 to 12 per cent. zinc. The mill is producing from seven to eight tons of lead concentrate daily. The sixth ton of lead concentrate, since resumption of work, has been shipped and the mill, in addition, is said to be making a zinc concentrate with an estimated gross value of $25 a ton.

The proposed reorganization of the Utica Mines Ltd. is said to be meeting with the approval of shareholders and a meeting is to be held shortly at Kaslo, to further the taking over of the property by H. H. Armstead, of New York. Rev. C. F. Caldwell, known in British Columbia as a mine operator and in the United States as the Zionist leader, is to attend the meeting.

Test Shipments to Ottawa. — The Mines Department, Ottawa, has issued regulations governing the shipment of ores to the Dominion Ore Testing Plant at Ottawa. Shipments weighing at least 50 pounds and not more than a ton may be sent by either freight or express. The Government will pay the railway charges from the point of shipment and cartage charges in Ottawa. In addition the laboratory tests will be carried out without expense to the shipper. Before any large shipment is made, however, a sample must be submitted and a reliable man must affirm that the ore being shipped is from a property showing indications of commercial opportunity. The Government will test the small shipment and, if considered of merit, will request a larger shipment. In the tests all the products become the property of the Government. It is stated that the regulations are designed to give the mining industry of the West the same facilities, with respect to the central ore testing plant, as those given mining operators of the Province of Ontario.

Ymir. — W. T. McDowell, who is interested in the Yankee Girl Mine, Ymir, states that the property was examined recently on behalf of New York interests and that it is likely to be sold.

Trail Ore Receipts. — Ore receipts at the Trail Smelter, Consolidated Mining and Smelting Co. of Canada, for the week September 15 to 21 inclusive, totalled 3,905 tons. Details follow:

Alamo, Alamo	46
Company Mines	2,710
Cork Province, Zwicky	35

	3,905

Kimberley. — E. W. Beatty, president of the Canadian Pacific Ry. Co.; D. C. Coleman, vice-president; Sir Augustus Nanton and Sir Herbert Holt, directors; W. R. McInnes, vice-president; and others visited Kimberley in the latter part of September. They inspected the new concentrator of the Consolidated Mining and Smelting Co. and went over other developments in connection with the Big Sullivan Mine operation.

Over 6,000 Miles of Roads and Trails. — It is interesting to note that the British Columbia Government, since the advent of the present Liberal administration, has constructed and maintained mining roads and trails in the Province having a total mileage of 6,348.93, almost enough road and trail in the aggregate to stretch from Victoria to Halifax and back again.

MAP OF WATABEAG AREA

The Ontario Department of Mines has just published the new map of Watabeag Area on the scale of a mile to the inch. This map was published last winter on a much smaller scale in black and white, in order to make it available to prospectors during the season just closing. The sheet covers an area of 18 miles by 24 miles, between the Gowganda and Porcupine areas. The T. & N. O. Railway crosses the northeast corner of the area, in which is Ramore station. Marginal notes give the geology and economic geology in brief. Most of the area is covered with sand and clay. Small amounts of gold have been discovered in a number of places, but so far none of it is of economic importance. In places the geological formation is favourable to the occurrence of gold.

DECENRALIZING OF INDUSTRY

In these days of ever larger and more congested cities, the decentralization of industry is looked to by many as the ideal solution of our industrial problems. These would be solved if our industries were split up into smaller units and were located in small towns or villages. It is thought that people would then lead a more healthful and contented life and would not be shut off from proper recreation facilities.

There is a tendency toward such decentralization latent in the development of hydro-electric power generation. The primary purpose of most such developments is to supply current for public utilities. But there is generally a surplus over the public utility demand which can be used for manufacturing purposes.

Some hold that all of this hydro-electric power will soon be needed and used for public utilities. This is not entirely true. Many of the larger of the new developments will undoubtedly sell most of their power for public service. But there are scores of smaller locations which are distant enough from great centers to enable an industry locating there to compete with the public utilities in purchasing power. When such power sites are not too far from the market and from good transportation, they will undoubtedly form the basis of future industrial towns.

An example of how this works out in even a fairly large waterpower development is furnished by Shawinigan Falls, Que., Canada. At this site the head is 150 ft. and is utilized to develop 195,000 hp. by the Shawinigan Water & Power Co. and 40,000 hp. by the Northern Aluminum Co. About half the former is transmitted to Montreal. The remainder has served as the basis upon which a number of industrial plants have been established, and these plants and the community which has grown up about them give a good idea as to what may be expected if this type of development spreads.

Perhaps the most interesting of the plants is that of the Canadian Electro Products Co. This concern produces acetic acid as a main product, and such other chemicals as paraldehyde, acetic anyhdride, acetaldehyde and butyric acid, which can be made from acetic acid or are by products of the process. Starting with acetylene, which is supplied from a neighboring plant, acetic acid is synthesized by a catalytic process. At the present time the plant is shipping upward of 1,500,000 lb. of this product per month.

The Canada Carbide Co. manufactures calcium carbide and acetylene. This plant has been adapted to the use of the materials which can be obtained in the locality—native limestone and gas-works coke. From these materials are manufactured first quality calcium carbide in all the usual commercial sizes. In addition, acetylene is manufactured in a large generating plant—one of the largest in existence—and supplied to the local branch of the Prest-O-Lite Co. and to the Canadian Electro Products Co.

Another very fine plant located at Shawinigan Falls is that of the Belgo Canadian Pulp & Paper Co. This plant is one of the largest producers of newsprint in existence. This mill is notable for the care with which scientific control is applied to the process and for the alert engineering talent which quickly takes advantage of each new development in paper technology. Perhaps the most interesting feature is the largest newsprint machine in the world, 233 in. wide and—running at 800 ft. per minute—producing 100 tons of newsprint per day.

But interesting as the various manufacturing plants at Shawinigan Falls are, the most interesting thing to the visitor is the community itself. Well-paved streets, good schools, including a technical institute, and several churches indicate, as do the high quality of housing, a prosperous and contented working population. The town has about reached its limit of growth, as the available power for industrial use is all taken up. So the present conditions of plenty of work and plenty of space for all stand a good chance of being preserved and Shawinigan Falls will remain, as it is today, an ideal industrial community.

—Chemical and Metallurgical Engineering

SILVER-LEAD FIND IN AUSTRALIA

In July of this year an important find of silver-lead ore was made about 40 miles northwest of Chillogoe, Queensland, Australia, the site of the State smelter. This is in the peninsula that constitutes the northeastern extremity of Australia, not far south of the equator, where rich silver-lead and copper ores have been mined. The ore is reported to average 65 per cent. in lead and to carry from 18 to 130 ounces of silver per ton of ore. A motor road 45 miles long from Chillagoe to the deposits is under construction by the State. The ore is so rich that the stakers have been able, with very little capital, to develop their property by means of the sale of ore. It is expected that the region will disclose important amounts of this silver-lead ore.

FIRST HYDRO-ELECTRIC PLANT IN SOUTH AFRICA

The first large hydro-electric plant in South Africa is being built by the Rhodesia Broken Hill Company on the Mulungushi River, which is on the Zambesi watershed. The flow of water is inconsiderable, but the head is 1,170 feet, and the Pelton wheels to be installed will develop 10,000 horsepower.

PROVINCE OF QUEBEC
MINES BRANCH
Department of Colonization, Mines and Fisheries

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, etc.

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

MINER'S CERTIFICATES. First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. The price of this certificate is $10 and is valid until the first of January following. This certificate gives the right to prospect on public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres.

WORKING CONDITIONS. During the first six months following the staking of the claim, work on it must be performed to the extent of at least twenty-five days of eight hours.

SIX MONTHS AFTER STAKING. At the expiration of six months from the date of the staking, the prospector, to retain his rights, must take out a mining license.

MINING LICENSE. The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cents an acre per year, and a fee of $10.00 on issue. It is valid for one year and is renewable on the same terms, on producing an affidavit that during the year work has been performed to the extent of at least twenty-five days' labour on each forty acres.

MINING CONCESSION. Notwithstanding the above, a mining concession may be acquired at any time at the rate of $5 an acre for SUPERIOR METALS, and $3 an acre for INFERIOR MINERALS.

The attention of prospectors is especially called to the territory in the North-Western part of the Province of Quebec north of the height of land, where important mineralized belts are known to exist.

PROVINCIAL LABORATORY. Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY, 228 ST. DENIS STREET, Montreal, for the determination, assays and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensure results of undoubted integrity and reliability.

The bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of the Province, on application addressed to

HONORABLE J. E. PERRAULT,
MINISTER OF COLONIZATION, MINES AND FISHERIES, QUEBEC

BRITISH COLUMBIA
The Mineral Province of Western Canada

Has produced Minerals valued as follows Placer Gold, $76,542,203; Lode Gold, $109,647,661; Silver, $59,814,266; Lead, $51,810,891; Copper, $170,723,242; Zinc, $24,625,839; Coal and Coke, $238,289,565; Building Stone, Brick Cement, etc., $36,605,942; Miscellaneous Minerals, $1,358,839; Making its mineral production to the end of 1922 show an

Aggregate Value of $734,259,619

The substantial progress of the Mining Industry of this Province is strikingly exhibited in the following figures, which show the value of production for successive five-year periods: For all years to 1895, inclusive $94,547,241; for five years, 1896-1900, $57,605,967; for five years, 1901-1905, $96,509,968; for five years, 1906-1910, $125,534,474; for five years, 1911-1915, $142,072,603; for 5 years 1915-1920, $189,922,725; 1921, $28,066,641; for the year 1922, $35,158,843.

Production During last ten years, $339,280,940

Lode-mining has only been in progress for about twenty-five years, and not 20 per cent. of the Province has been even prospected; 300,000 square miles of unexplored mineral bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than those of any other Province in the Dominion, or any Colony in the British Empire.

Mineral locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full information, together with Mining Reports and Maps, may be obtained gratis by addressing

VICTORIA, British Columbia.
THE HON. THE MINISTER OF MINES.

Cutting Coal Cutting Costs

When you can drive entries, take down roof, shear, cut out dirt and clay bands and undercut at any angle with one machine, as you can with the "Ingersoll-Rand Radialaxe," you can reduce production costs by using that machine.

Shearing and blasting on "open end" means more hard lump coal with less powder. The "Radialaxe" will cut out the band for a width of 12 ft. to a depth of 6 ft. without moving the column set up. There is no other machine that does this so well.

One well-known coal company using over 300 Radialaxes found on careful investigation that the average maintenance cost was less than a dollar and a half per month for each machine. Many of these machines had seen several years service.

Write for bulletins or ask for a demonstration.

DODGE

Carries a Half-million Dollar Stock of Shafting, Hangers, Pulleys, Clutches, Couplings and Other Power Transmission Units

When a buyer needs standard Power Transmission Units, he generally wants them in a hurry.

That's the time for him to come to us. Then he'll find out how speedy and reliable Dodge Service really is.

From Toronto or Montreal we can ship, on the day an order is received, any quantity of any or all standard sizes of Dodge Wood Split Pulleys, Cast Iron Pulleys, Universal and Double Brace Hangers, Friction Clutches, Cut-off Couplings and Shafting.

We can do this, because we have the financial resources to carry this large stock, and because we are willing to manufacture for stock at time when others might close down for lack of orders.

Nearly 40 years' experience has taught us the lines that are most in demand, and so we are rarely caught napping by an unusual "Rush Order."

You've no idea how reliable Dodge Service can be, until you put it severely to the test.

Paste up this advertisement as a reminder and as a promise of satisfactory service when the time comes.

MINES BRANCH

Recent Publications

Talc and Soapstone in Canada, by H. S. Spence.

Titanium, by A. H. A. Robinson.

Summary Report of Investigations made by the Mines Branch during the calendar year ending Dec. 31, 1921.

Phosphate in Canada, by H. S. Spence.

The Preparation, Transportation and Combustion of Powdered Coal, by John Blizard.

Road Materials along the St. Lawrence River, from Quebec Boundary to Cardinal, Ont., by R. H. Picher.

Barium and Strontium in Canada, by H. S. Spence.

The Coal-fields and Coal Industry of Eastern Canada, by F. W. Gray.

Analyses of Canadian Fuels. Part I to V, by E. Stansfield, M. Sc., and J. H. H. Nicolls, M. Sc.

Graphite, by H. S. Spence.

Gas Producer Trials with Alberta Coals, by J. Blizard and E. S. Malloch.

The Mines Branch maintains the following laboratories in which investigations are made with a view to assisting in the developing of the general mining industry of Canada:—

Fuel Testing Laboratory.—Testing value of Canadian fuels for steam raising and production of power gas; analyses, and other chemical and physical examinations of solid, liquid and gaseous fuels are also made.

Ore-Dressing Laboratory.—Testing of Canadian ores and minerals, to ascertain most economical methods of treatment.

Chemical Laboratory — Analyzing and assaying of all mineral substances and their manufactured products. Copies of schedules of fees, which are slightly in excess of those charged by private practitioners, may be had on application.

Ceramic Laboratory.—Equipment is such that complete physical tests on clays and shales of the Dominion can be made, to determine their value from an economic standpoint.

Structural Materials Laboratory.—Experimental work on sands, cements and limes is also undertaken.

Applications for reports and particulars relative to having investigations made in the several laboratories should be addressed to The Director, Mines Branch, Department of Mines, Ottawa.

Applicants for publications not listed above should mention the precise area concerning which information is desired.

Summary Report — The annual Summary Report of the Geological Survey is now printed in parts. Applicants should, therefore, state what particular geologist's report is required, or what subject they are interested in.

The Geological Survey will, under certain limitations, give information and advice upon subjects relating to general and economic geology. Mineral and rock specimens, when accompanied by definite statements of localities, will be examined and their nature reported upon.

Communications should be addressed to The Director, Geological Survey, Ottawa.

Ontario's Minerals

PROVINCE OF ONTARIO

Hon. CHARLES. McCREA, Minister. DEPARTMENT OF MINES *Thos. W. Gibson*

Mineral Areas

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favourable for the occurrence of minerals 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver veins of Cobalt, Gowganda and South Lorrain occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

Economic Minerals

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario: — actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluorspar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, Portland cement, brick and tile, meet every demand.

Mineral Production

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1922 to be worth $62,202,169, of which the metallic production was $38,190,711.

The following figures show the growth of Ontario's mineral industry by five-year periods since 1891 when a Bureau of Mines was first established.

Year.	Value.	Year.	Value.
1891	$4,705,672	1911	$41,976,797
1896	5,235,003	1916	65,303,822
1901	11,831,086	1918 (Maximum war output)	80,308,972
1906	22,388,383	1921	48,128,387

Dividends and bonuses paid to the end of 1922 amounted to $28,096,699 for gold mining companies, and $86,238,185 for silver mining companies or a total of $114,334,884.

Mining Regulations

A miner's license costs $5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of $2.50 or $3.00 per acre, depending on location in unsurveyed or surveyed territory.

Assay Office

The Provincial Assays Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

Publications

For list of publications, illustrated reports, geological maps and mining laws, apply to

Thos. W. Gibson,
Deputy Minister of Mines.

What Are Your Flotation Troubles?

Have you difficulty in obtaining flotation oil which exactly meets your requirements? Do you have trouble in obtaining uniformity among different lots?

Our technical staff, always at your service will gladly co-operate with you in determining the grade of flotation oil best suited to your needs. This done, we can supply it.

Hercules Pine Oils, manufactured under strict chemical control, can be furnished you in lots which never vary from the original specifications.

Write for quotations and an interesting booklet on flotation.

A Bank That Is Always Near

The mining engineer — moving as he does from place to place — must needs utilize a bank which has branches conveniently located in mining centres.

The Imperial Bank, with 192 branches throughout Canada and with special concentration in mining districts, offers distinct advantages to those engaged in the mining industry. Patrons of this Bank are never far from their bank accounts, no matter to what part of the Dominion they may go.

Why not ensure adequate banking facilities by depositing your funds with this Bank?

TORONTO MINING TANKS

The life of Wooden Tanks depends [illegible] on the quality of the Lumber used in their manufacture.

The Fir used in the manufacture of TORONTO Tanks comes from British Columbia — only the finest quality procurable is sawn for our No. 1 Clear Tank grade stock — a tight grained wood — free from sap, shake, knots and all knots, excepting a few fine pin knots.

Cypress and White Pine are similar in quality to our No. 1 Fir although more adaptable in special installations.

TORONTO No. 1 Tank Grade lumber is the finest quality sawn - thoroughly air dried before being made into tanks. The user is assured of a most satisfactory product.

TORONTO Tanks are made for any purpose - of any size for all needs. Send for catalogue.

CERAMIC INDUSTRY GROWING RAPIDLY

During the last few years there has been a healthy growth in Canada's ceramic industry, which promises even better things for the future. The heavy materials, such as brick, tile of various kinds, sewer pipes, fire-brick, terra-cotta, fire-proofing, etc., have been made for years on a scale commensurate with our needs. But it is only comparatively recently that the finer grades of ceramic products have been made on any adequate scale.

Though development in the west is full of promise, our chief centre of ceramic manufacture still remains in the east. In Ontario and Quebec, however, practically all the raw materials, including fuel, are imported, so that a successful ceramic industry in these provinces at present depends almost entirely upon the protection of tariffs and the advantage of a near-by market. In the west, on the other hand, the chief ingredient, clay of various grades, and the best of fuel, natural gas, are available in abundance, and these advantages promise to provide the basis for a thriving and extensive industry.

One can best gauge the progress of ceramic manufacture in this country by considering a few representative examples. Canada is one of the world's leaders in the use of electricity. Now she possesses porcelain factories that are turning out 220,000-volt insulators, equal to the best. Two firms are making insulators of this and other kinds, one in Hamilton and one near Niagara Falls. One of these firms recently purchased a porcelain factory in Limoges, France, in order to provide their European customers more economically with high-voltage insulators. In addition there are factories producing low-tension insulators and other porcelain ware.

Canadian-made vitrified sanitary ware has now a firm hold on the home market, as have enamelled iron ware of the heavier varieties such as lavatories and bath-tubs, and of the lighter kinds, such as kitchen ware. There are numerous manufacturers of these products in Ontario and Quebec.

The common domestic and electrical glass ware in use in this country is now made mostly within our borders. For it, too, the chief raw material, sand, is mostly imported, but the chemicals, lime and soda, are Canadian-made.

The vitrified floor tiles now being used in this country are got mainly from a factory in Kingston, Ontario, which is capable of supplying the whole Canadian trade. The chief ingredient of these tiles is feldspar, which is obtained locally and ground at the factory. There is insufficient tariff protection to allow the manufacture in Canada of the corresponding glazed wall tiles.

The pottery industry is the branch that has made the most notable advance during the last year or two, with promise of a rapid and large expansion. Recently small potteries have been established at Banff, Alberta and at St. Andrews, New Brunswick, producing very creditable art pottery, such as vases, trays and jugs and catering to the tourist trade. A pottery plant is now being completed at Oshawa, Ontario, where it is proposed to produce tableware on a fairly large scale. It is understood that other companies are formulating similar plans. For years there have been potteries at St. John, New Brunswick; Iberville, Quebec; Hamilton, Ontario; and Medicine Hat, Alberta, making stoneware and other heavy domestic pottery such as teapots, mixing bowls and hospital ware. A feature of the Medicine Hat plant is an abundant supply of natural gas which warrants the shipment westward, away from the chief market, of the pottery clay and ball clay of southern Saskatchewan. Their very low fuel cost permits them to compete successfully in the Ontario and Quebec markets.

At present Canadian specialists in ceramics, and particularly in pottery manufacture, are few and far between. This condition will be rectified rapidly when the ceramic school of the University of Saskatchewan commences to turn out graduates. Meantime the Ceramics Division of the Mines Branch, Department of Mines, Ottawa, which is in charge of Mr. Howells Fréchette, is available for free consultation by those interested. This department of the Mines Branch has done yeoman service during recent years in helping to put Canada's ceramic industry on its feet.

THE CANADIAN MINERAL EXHIBIT

The exhibit of minerals will be an outstanding feature of Canada's display at the British Empire Exhibition next year. Already a large part of it is in Ottawa, ready for shipment to England, and every day additional lots are received from the Dominion's various mining districts.

Ontario, as the premier mining province, will no doubt display her riches to good advantage to the millions of people who will visit the Exhibition. Mr.

Thos. W. Gibson, Deputy Minister of Mines in Toronto, is taking a particularly active interest in sending on choice specimens and in stimulating mine managers and others to do likewise. Some of the ores of the province are well adapted for display, and full advantage is being taken of this fact. The wonderful specimen of silver ore from the 54-inch vein section of the Keeley now reposing in the parliament buildings is too large and unwieldy to take across the ocean and back again. Instead, South Lorrain is well represented by a particularly beautiful 1,200-pound specimen from the Frontier mine which carries 8,000 ounces of silver to the ton. This will compose the central figure in a comprehensive exhibit from the camp. Cobalt will, of course, be adequately represented, a feature being a series of specimens from the 1,600-foot level of the Beaver mine to illustrate conditions at the lower silver-bearing contact of the diabase sill. Porcupine, with its "big three" mines and shoots of spectacular ore; Kirkland with its tellurides; Night Hawk, Larder —all will add their quota to the best gold exhibit Ontario has yet produced. An exceptionally fine lot of nickel ores, smelter products and finished materials has been provided by the three large nickel companies. Non-metallics such as talc, feldspar, graphite and mica will round out the display.

British Columbia's mineral industry is notable for its variety and for the large number of its mines, large and small. Dr. J. Fleet Robertson, the Provincial Mineralogist, is in a particularly favourable position to make use of this in gathering the exhibit for his province, which is now in Ottawa entire. He has had active deputies in the resident mining engineers in charge of the various mineral districts. In addition to the ores of gold, silver, lead, zinc and copper that account for most of British Columbia's output, there are numbers of the less well known minerals such as magnesium sulphate, fluorspar and ochre, which are adding their modest quota to the province's annual production. This will be by far the best exhibit British Columbia has had, even though some former exhibits are hard to beat.

The first specimens of silver-lead ore from the Mayo field in the Yukon were sent to the San Francisco exhibition. The new Mayo will show next year, by grace of the finds on Keno Hill, specimens that should stimulate a general interest in our new sub-Arctic mining field.

Manitoba is the latest of the provinces to give definite promise of producing metallic wealth. In spite of comparative inaccessibility and the reaction that inevitably follows over-speculation, its development is proceeding steadily under the wing of the Commissioner, Mr. J. A. Campbell of The Pas, who has supplied a representative collection of the gold, copper, zinc and other minerals already located in the mineral belt.

Quebec's mineral stand-bys for many years have been asbestos and copper pyrites. To these will be added this year zinc-lead ore from Gaspé, which has provided some unusually fine specimens, and gold ores from the new finds in the north that are making such a stir at present. These latter will have the added interest of uncertainty; it is not known yet whether or not the deposits will disclose "another Hollinger", or several of them. Quebec also has working deposits of feldspar, mica and other non-metallics whose products will lend variety to the exhibit.

The most important of all our minerals, and the least impressive to look at, is coal. Canadian coals will be shown on a comprehensive scale, from the vast fields of Alberta, the smaller basins in the western mountains, and the strategically situated maritime fields of Vancouver Island and Nova Scotia.

A special feature will be a collection of the raw materials and products of the ceramic industries. This will represent the Dominion from coast to coast in one exhibit. Seldom do we realize the importance of clay products in everyday life. We have now a surprisingly complete line of ceramic manufactories in Canada from the bricks that compose the walls of our houses to the electric bulbs that light their interiors.

We wish to make it known to the British people that Canada has already an important and diversified mineral industry, whose future promises still better things. There are few practical measures that could aid more in accomplishing this end than the mineral display to be seen next summer in the central Canadian pavilion at Wembley.

THE PROPOSED ASBESTOS MERGER

It has been admitted officially that the asbestos industry of Quebec has suffered severely during the last year or two by reason of unnecessary and unreasonable cutting of prices. This is bad business — bad for the asbestos producers as a whole, whose profits are reduced, bad for the Province of Quebec, whose taxable income is lessened, and bad for the Dominion, which thus disposing of a natural resource at less than its worth. Any reasonable and sound measure of cooperation among the asbestos companies that will eliminate undue competition for markets will benefit themselves the Province and the Dominion.

In spite of keen competition from other fields, particularly Rhodesia, the Quebec asbestos district still holds the larger part of the world's markets. The quality of its product is almost, if not quite, unique. It is close to the largest market, the eastern United States. It has vast reserves of ore of a grade equal to that now being worked. It can, if it is allowed, hold the field against all comers. Excessive competition among Canadian producers will not aid the industry; it will result merely in robbing the mines of their best grade of ore and presenting it at a reduced

price to our neighbors in the United States and to other buyers overseas.

It is with great satisfaction, therefore, that we note the reports now current that negotiations for a merger of all the asbestos producers show some signs of success. The *Financial Times* reports that Asbestos Corporation has made a definite offer to the other companies to acquire their holdings, and that this offer is being considered seriously. We hope that the negotiations will lead to a merger. There is plenty of competition from without to induce energetic and efficient management. What is most needed at present is unity within the Quebec asbestos industry, and the strength that union brings.

A united Canadian asbestos industry can do a great deal more than drive a shrewd bargain with buyers; it can increase its profits in other ways. The principal mines lie in a congested area at Thetford Mines. Some of the properties have inadequate surface rights, while their neighbors have land to spare. In other cases party walls are a nuisance. Mining and hoisting equipment is duplicated in adjoining pits, where a single set would serve the combined pits. There are numerous comparatively small crushing plants and mills, where a smaller number on a larger scale would treat the ore at lesser cost. Each of the present companies must maintain a complete office and selling staff. Last, but most important in our eyes, it is only the present state of disunion among the asbestos companies that has prevented a thorough-going, fundamental research into asbestos production — a research that must be undertaken and carried through before Canada will reap the full benefit of these wonderful deposits of asbestos ore.

If there were a market of appreciable dimensions in Canada for raw asbestos, one could hardly urge a merger with the object of raising its price; but there is not. The principal Canadian factories for working up the raw material are connected with the mining companies. There can be, therefore, no reason but human perversity that will prevent the proposed combination of interests. We trust the negotiations now in progress will result in a united Canadian asbestos industry.

TECHNICALLY DIRECTED PROSPECTING

The directing of prospecting by trained technical men is the theme of four American teachers and engineers whom we quote in these pages today. Fortunately for the progress of our mining industry, it is a theme that is becoming rapidly a favourite topic for discussion among those whose interests lie essentially on the outskirts of the industry, where pioneering is the order of the day. While some worthy mining men bemoan the passing of the old-time prospector, with his rule-of- thumb methods, his perseverance and his temerity (mixed, we may add, with equally important objectionable qualities), others with a clearer vision see the new régime that is coming. The search that was left formerly to the impulse of the natural born prospector will, in the future — the near future, we venture to predict — be organized and directed in much the same orderly and rational fashion that now is the vogue in mining operations. The trained technician will take hold of the search for ore much as he took hold of the mining of it a quarter of a century ago.

We do not mean, of course, that every prospector should be a mining engineer or geologist, any more than that the whole force of a mine should be college graduates. But, as it requires a well-trained man with practical experience to get the most out of a mine, so it is necessary that the efforts of the average prospector should be directed in order that they may be expended to the best advantage.

At present there are only a handful of men in Canada competent to direct systematic prospecting. Most of these are geologists, and a few are mining men. The two principal requirements are that they have at their command the requisite scientific knowledge, and that they have a thorough and practical knowledge of how to prospect. Few scientifically trained men have the latter; their scholastic training seems to dull the natural instinct that provides at once the prospector's impulse and his faculty for finding mines. The formal studies guide the feet of the young man on the road to the mine and mill rather than along the trail that leads at last—perhaps only at long last—to the hidden treasures of the woods and the mountains.

This question is worth the serious consideration of mining engineers, mining investors, and those responsible for the teaching in our mining schools. We make no apology for bringing the matter once more to the attention of the *Journal's* readers.

SURPLUS EARNINGS OF MINERAL INDUSTRY

The mineral statistics that we look upon often as dry-as-dust and not of much account in the real affairs of the mining world are actually veritable storehouses of information and often they contain, hidden away in their columns of figures, ideas that are of much general interest. Recently we dipped into the report of the Dominion Bureau of Statistics for 1921, the last year at present available, and found a picture in tabloid that may interest others. In that year of depression the mines, mills and smelters employed 56,976 persons, who earned $79,161,640 and produced materials to the value of $170,714,084. The invested capital was $559,514,151 and fuel and other expenses were $61,780,862. Allow 12 per cent. interest on the investment and there remains over $40,000,000, which might be considered as available for reinvestment in the mineral industry. We should like to see a more expert exposition than our own of this point.

The Uses of Concrete in and about a Coal Mine

II. — Underground Structures

By LUKE LINDOE*

Coal mine operators have not been slow to avail themselves of the admirable qualities of concrete for above ground structures. With an eye always open for a chance to reduce overhead expense from maintainance, repair and insurance charges, they were not for behind other industries in adopting this substantial building material. Intelligently designed and constructed with thought for future requirments and additions, concrete buildings pave the way for the continuity of operation and low final cost so necessary to efficient mining operation.

It is below ground, however, that we do not see it used to the extent that its merit warrants. This in part is due to the time honoured custom of using timber for all classes of work, to the class of labour usually obtainable below ground, and also to the fact that opportunities are missed to use concrete in work of a permanent nature. Time and again one will see timber used in mine structures or supports that has to be renewed again and again. This work, quickly and cheaply done at first, must be repeatedly renewed, until at last, through delays and increasing labour charges, it costs twice or thrice what a permanent piece of work would have done in the first place. There are many places in the mine where, owing to the temporary nature of the requirements, the use of concrete is, of course, out of the question. These can usually be detected at once and the thought of concrete dismissed. If, however, all cases were carefully analyzed we would see more concrete used than at present.

Mix Concrete at the Surface, if Possible

The placing of concrete is attended with more difficulty below than above ground, owing to lack of space and light, and other difficult working conditions. These disadvantages are partly offset by the simple form an underground structure usually takes, pleasing appearance not being of much account below ground. Strength and permanency are the features to be aimed at, and to obtain these, certain requirements are necessary. It would, for instance, be unwise to build a concrete dam or stopping in a mine where the roof and floor were very strong and the coal soft and friable, or if weight were bearing on the coal, and settlement taking place. The very characteristics that make it so valuable under the proper conditions would cause its failure here, since, being rigid, it would be crushed under the enormous weight. It will be seen, therefore, that the requirements below ground are quite different from those above ground, and that the natural conditions must regulate the type of structure installed . When once this is done , the satisfaction gained from not having to make renewals will amply repay the additional first cost of concrete.

In these days of permanent highway building, concrete has become a popular material for their construction, and in an attempt to cheapen the cost of laying, engineers and contractors have evolved the central mixing plant. There would rarely be a job of such magnitude in even the largest mines as to warrant the erection of a central mixing plant; but the principles involved can be used to accomplish an entirely different end. It has been found that about one and one-half hours can elapse between the times of mixing and of placing the concrete without any undesirable effects showing in the finished work. This opens up the possibility of using a mixer on the surface, loading the mix into a car and sending this into the mine to be placed in the forms. If the work is being done on idle days or week-ends, there will be no difficulty in getting the concrete on the job in much less time than was mentioned above. This permits an important part of the work, the mixing, to be done where the working conditions are good and the various materials are accessible. In mixing below under the usual conditions of unskilled labour and inadequate supervision, the cleanliness and thoroughness so essential to good mixing are not so likely to be observed.

As was mentioned above, in the design of concrete structures for use below ground, simplicity and strength should be the key-notes. Rarely are the physical conditions stable as on the surface, where good bearing for foundations is the only real factor to be taken into consideration outside of the superstructure itself. Both roof and floor may show slight movement, and in almost all cases gradual subsidence of the roof will occur necessitating provision being made in design to take care of this. The walls of any building such as a pump house or repair shop, will need to be thick enough to carry the weight that may be induced by opening up the additional ground for the site, even though this settlement is not occurring at the time of construction.

The cases deemed worthy of consideration under the caption of this article are any structures of a permanent nature required to house machinery, such as hoist or pump houses and repairs shops, dams, air stoppings, landings at the top and bottom of slopes, stables for horses and linings for entries or tunnels driven through strata that disintrgrate in time through the action of the mine air on their surfaces. As machinery foundations are almost always built of concrete, whether above or below ground, they will not be specially mentioned, nor will shaft linings and bottoms be discussed, as they usually have to have individual treatment and are deserving of a special article.

Pump Houses

Coal mining laws usually require that any building housing electrical machinrey shall be of fireproof construction and well ventilated. As modern pumping is usually done by electrical power, this at once places the materials to be used in a restricted category. Even if some other power, such as steam or compressed air, is used, the likelihood is that, since for economical considerations or in view of proposed future changes electrical drive might be adopted later, it might be considered necessary to design the building with a view to such a change.

The site for a pump house should be chosen so that it will not be affected by the mining operations, either present or future. Indeed, this applies to the whole pumping arrangement, as any great movement or crushing of the strata might not only be detrimental to the pump house, but might affect seriously the sump also. The latter would not only endanger the lives of work-

* Engineer, International Coal & Coke Co., Coleman, Alberta.

ien, but would be costly, and would affect seriously he mining operations. A pillar of adequate size must e left round both to insure that any squeeze occurring n the working sections may be checked before affecting ither pump house or sump.

Fig. 1 gives the details of a concrete pump house designed to fill the main requirements. Footings and oundations have a bearing on the solid floor rock, which has been blasted level to receive them. The walls are of sufficient thickness to support the added area opened up. In this case, as there is a considerable space between the roof of the building and the roof of the seam, timber sets resting over the walls of the pump house will be used to support the rock above, these sets being lagged between to take care of any small rock that may work loose. Where the space is limited this sup-

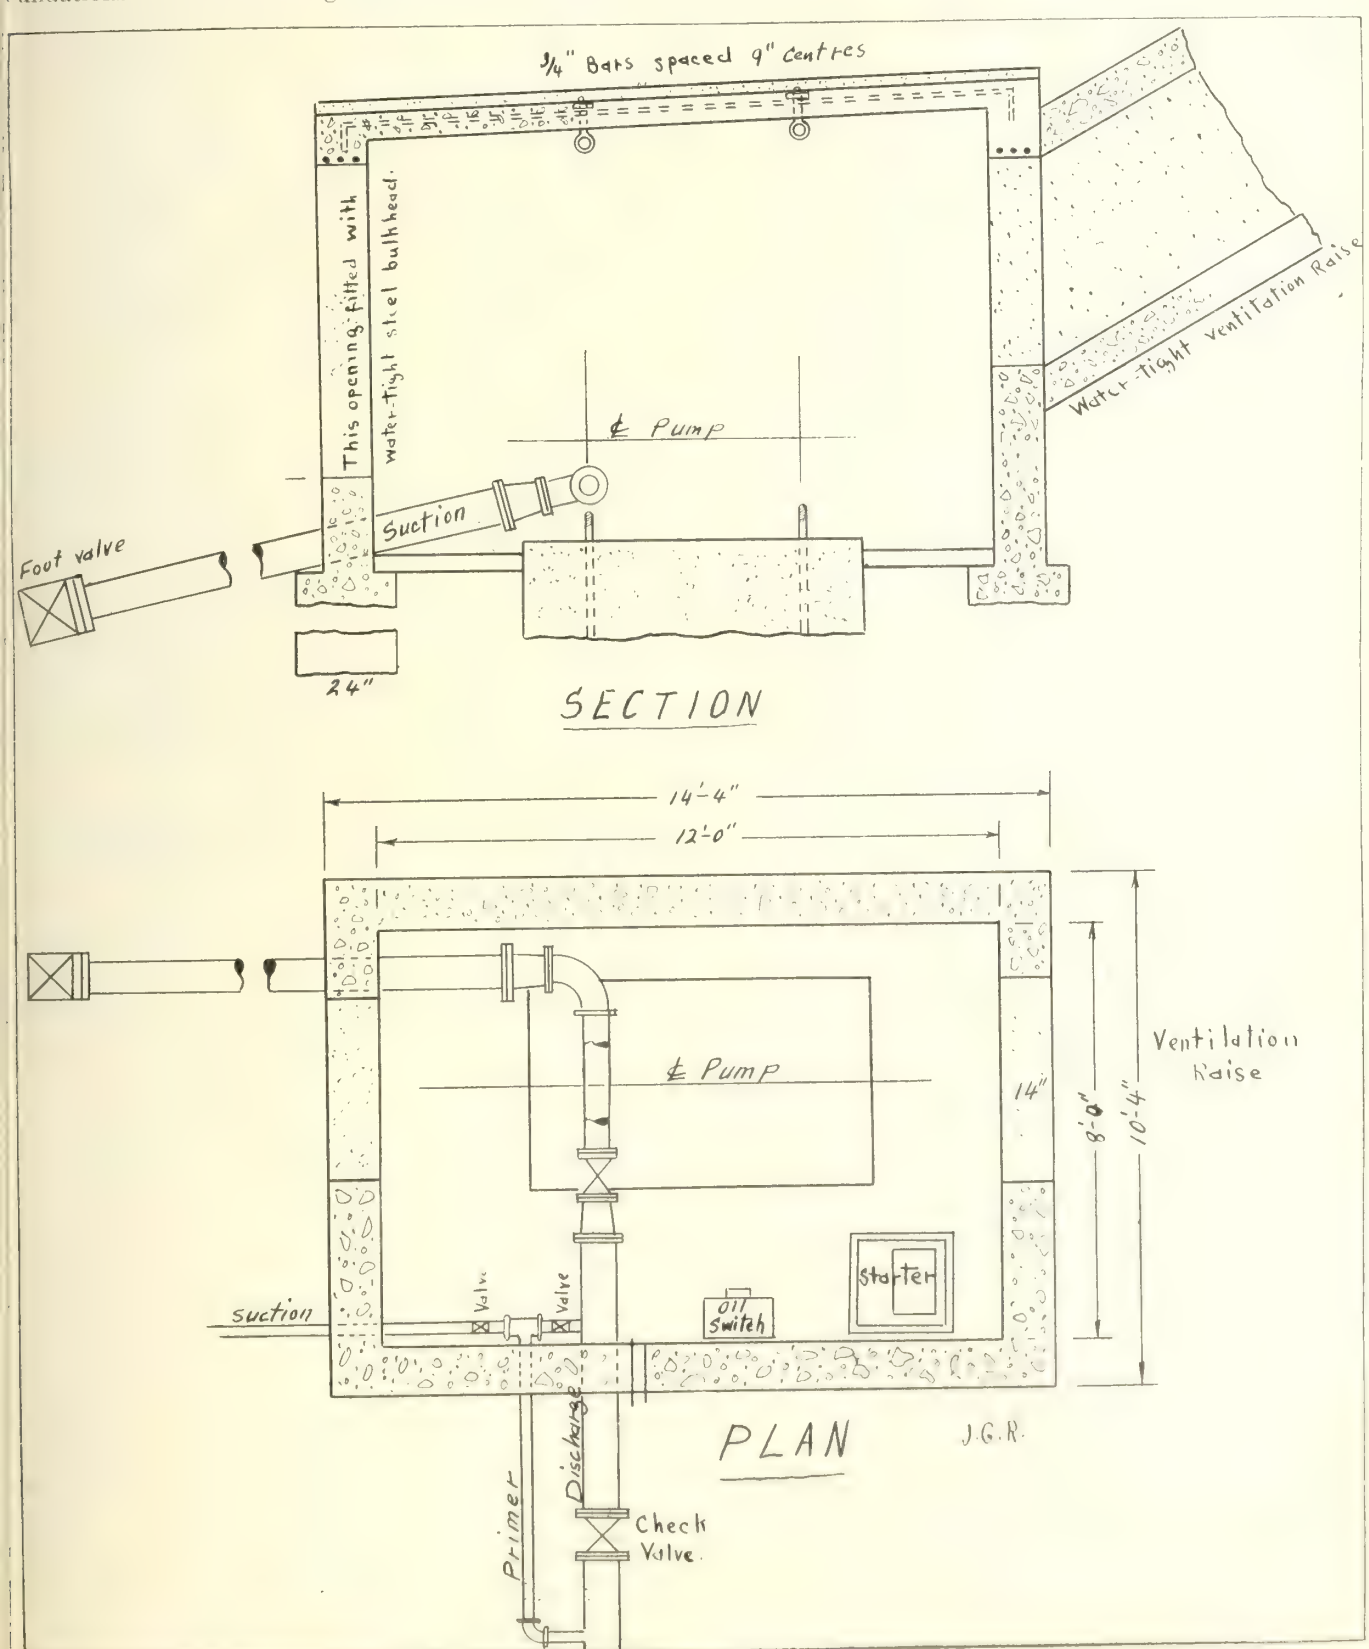

Fig. 1.—Underground Pump House.

Note provision for operating pump when water has risen to a level above the pump house by closing water tight bulkhead.

port could take the form of small timber cogs resting over the walls as above. A roof re-inforced with ¾" round bars gives protection to the machinery below. Over the centre line of the pump and motor the roof is increased in thickness to a width of 24" and provided with further re-inforcement, to form a beam into which eye-bolts are placed to afford an easy means of lifting heavy parts by block and tackle. A door opening opposite the centre line of the pump and tracks to this opening facilitate the removal of parts or the whole of the unit to the surface for repairs, etc. Another 4 feet by 4 feet opening in the opposite wall, connected to a ventilation raise, assures an adequate supply of air passing over the motor. In order to open no more ground than is necessary the building is made just large enough to give working room round the parts for repairs, oiling and starting, and the convenient placing of the starting and switching equipment. Electric lighting is advisable where possible and the lights should be placed so as to give proper illumination on such parts as valves, switches, gauges and starter.

Devices to Avoid Inundation of Pumps

While discussing this subject it might be interesting to comment of the precautions taken by wide-awake operators to so arrange their pumping installations that the pumps will not be immediately inundated in case of sudden abnormal inrushes of water. These might come from various sources; a cloudburst might cause creeks the flood over their banks and the rising water to enter the surface openings. Settlement of the strata over worked out areas may develop cracks and fissures to the surface, through which surface water may percolate. Old workings containing water may be tapped, increasing the daily amount to be pumped, and that must be provided for. The causes might be many, but whatever they are, the effects are to be avoided as being not only dangerous to human life, but costly to operation. The pump, once flooded, is out of action, and other equipment has to be installed to unwater that section, which takes time and usually results in the water getting so far ahead as to stop mining operations in that district for some time. Even when the water is once more down to normal level, a considerable time must elapse before the motor can be taken to the surface and dried out.

In looking for a solution of this difficulty, various means have been adopted, and most of them with good results. A method used at one mine is to build one or more dams, as required, on the entries leading to the pump, through which the water passes, to cause the water to rise in the workings above the pump. Depending on the arrangement of dams, which will differ at various mines, the water may be raised to some considerable height before affecting the pump. The mine referred to was able to make provision for a height of 300 feet before the water could flow down to the pump house. The suction pipe of the pump is carried through that dam which is placed at the same level as the pump house, and any height of water behind the dam assists the working of the pump by the increased pressure obtained.

An unused slope can also be utilized for the same purpose by placing a dam at the bottom of it, and carrying the pipes through as mentioned above. An exceptional case occurs at one mine across the border where large quantities of water are to be pumped daily. The owners sank a shaft, tapping the strata near the lower workings, which were to be used as a sump for storage of large quantities of water. The bottom of the shaft and these workings were connected by a small drift, and the pipes placed in this, the drift being afterwards dammed. Two large capacity pumps were installed in the bottom of the shaft, where they could be operated without being affected by the water in the mine.

Underground Hoist Houses and Repair Shops

The general requirements for hoist houses and repair shops are the same as for pump houses except as to size and interior arrangement. Hoist houses will require more working room around the machinery than the pump house, which in turn will require larger roof spans. This can usually be taken care of by placing a sufficient number of square or rectangular columns in proper relation to the roof area, and in convenient positions with regard to the machinery. In the case of repair shops for locomotives and coal-cutting machines etc., these columns can be so placed so as to come between the pits, or the interior could be divided into some convenient arrangement by solid partition walls.

Dams

Sometimes it becomes necessary to place a dam in the entry or entries of a mine to prevent the inflow of water from some very wet portion of the strata, or as mentioned previously, from abnormal sources. They are sometimes used in connection with pumping installations, for storing water during non-pumping periods. In some European countries an ingenious arrangement of tapered wooden blocks is built up to form a dam, the large ends being toward the pressure side, the whole tending to bind and become compact as the pressure against the surface is applied. Whether it is that the art of building these is not known on this side or that they are adaptable only to narrow seams, the fact remains that a large percentage of dams used on this side of the water are built of concrete, and some of brick.

Of particular importance in the building of an underground dam, in the selection of a suitable site. This should be in a place where the adjacent strata are free from crevices, faults, etc., through which the water might be forced when the pressure becomes great. These fissures would in a short time be worn large enough to pass considerable water behind the dam, and the stability of the dam would become endangered by the action of the water on the coal into which the dam is hitched. The walls, roof and floor at the site should be firm and solid, so that the dam may not be pushed bodily from its bearing by the pressure of abnormal storage.

The accompanying drawing shows a concrete dam that was built to withstand a pressure of 200 pounds per square inch, and probably typifies the maximum requirements for underground dams. As it was thought that the concrete might not be water-tight under such a high pressure, a thickness of waterproofed mixture was carried up on the pressure side as the main wall was being placed. A row of drain pipes fitted with valves were placed in the forms near the bottom, to pass the water during construction, these being closed at the completion of the work. Another row of 1" pipes placed vertically at regular intervals permits of the height of water being tested by opening the various valves with which they are fitted. A manway was provided consisting of a large diameter pipe to which a water-tight steel door was attached, allowing of passage through for inspection and repairs. When the concrete approached the roof of the seam where it was impossible to pour it in the usual way, grout was forced by compressed air through 2" pipes, which successfully made a water-tight joint. The same end could be accomplished by placing

iis portion of the wall with the cement gun now on ie market, which blows the mixture into place directly. f it were possible to use one of the latter machines, it ould be advisable to utilize it further by covering the djacent roof, floor and sides with a ¾″ coating for ay 30 feet at each side of the dam site.

Stoppings

While it would impracticable to build concrete stoppings throughout the mine, there are points in every entilating system of a mine, as on the main airway, especially near the fan, where, owing to high water gauge ressure and the necessity for a permanent stopping, heir use is justified. While more expensive to build han wood, they prove more economical in the end on ecount of their tightness and the consequent saving of ir.

The pressure exerted by the air on a stopping is slight, nd it should be placed where the strata are firm, so hat it does not have to sustain any undue weight. It ollows, then, that its construction can be fairly light, nd therefore, in comparision with other concrete structures, it is of low cost. Except in unusual conditions t need not be provided with a door, assuming, as mentioned above, that it is placed so as to form part of the ain airway, where it can be inspected as the airway s being travelled.

A typical installation consists of a 12″ concrete wall, he bottom resting on the floor rock and the sides being itched some distance into the coal at the sides. All he work of preparing the cuts or bearings in the coal or the walls should be done by hand so as not to disturb he strata, as would be done if blasting were resorted o. The top 8″ of wall may consist of a squared cedar timber, neatly grouted in place with cement mortar to form a tight joint with the roof, and also to allow of some settlement.

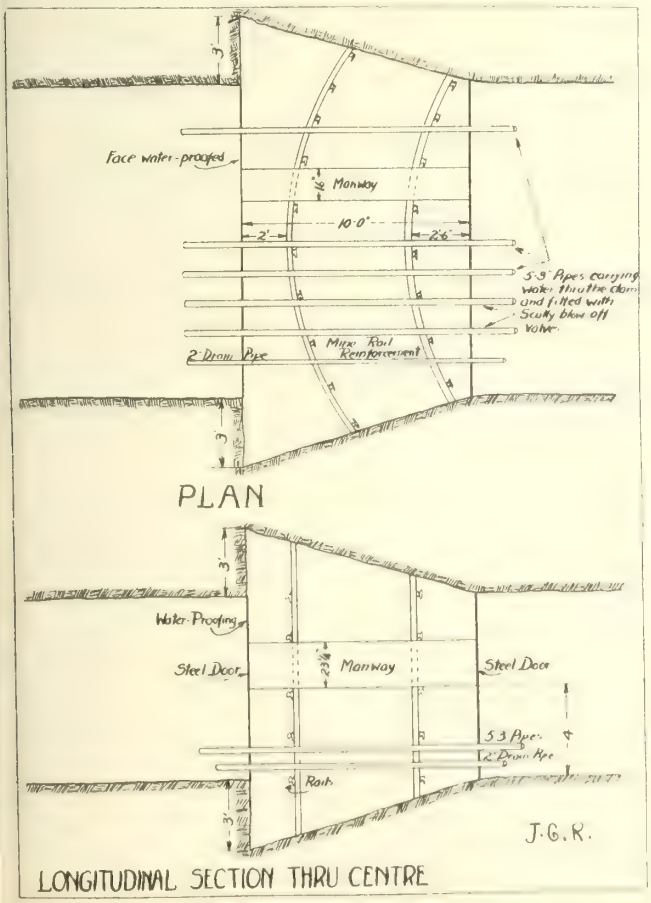

Fig. 2.—Concrete Mine Dam.

If it is necessary to provide means to pass through, an opening 28″ x 28″ can be formed in the wall forms, and a 2″ x 6″ frame set in, to which a 24″ square door of 3-ply T & G lumber with tar paper between is hung on the pressure side.

Slope Bottoms, Arches, Etc.

One of the most useful applications of concrete construction below ground is to arches at slope bottoms. Often the strata through which the landing is driven are not strong enough to support themselves, but have to be kept timbered. Again, what might have been good material when first exposed, becomes loose and friable in time, owing to the action of mine air constantly playing upon it. This causes the surface to disintegrate and it falls, endangering not only the bottom men working under it, but in time greatly increasing the original section and thereby making it more difficult to support. From the standpoint of cost, the chief drawback is the delay caused in cleaning up the damage done by wrecks resulting from runaway trips on the slope. If the slope is 30 degrees or more, a "dog" trailing behind the trip to derail it, in case of a break in rope or coupling, merely overturns the ears, and they proceed merrily on down the slope to the bottom, knocking out sets or anything in their path. The scene at the bottom is usually something to marvel at, timbers, rock and broken cars lying in an inextricable mass. Even with the best of organization, the best part of a shift is gone before the debris is cleared away, and enough timber set to make the place safe to work in again.

Where the bottom is protected by a concrete arch the labour entailed in clearing away is much less. While the cars will be broken as badly as under other circumstances, they are all that is to be handled, and an hour or two at the most is all that will be required to get running again. In mines where these runaways occur at all, they do so rather frequently, and if the loss in output and repair work were kept accounted, it would make startling reading.

Protection of Slopes and Entries by Thin Coatings of Concrete

About two years ago a new method of applying concrete in thin coats were introduced. A mixture of cement, sand, very fine gravel and water is applied under air pressure by a machine known as the "cement gun," the mixture itself being called Gunite.

Like all new things, it was slow in getting a footing, but to-day it is being applied with success to a great diversity of uses. It is known to be an excellent surface protection for all manner of works, from dams to irrigation ditches, and from structural steel to the outer surfaces of dwellings and other buildings.

The coal mining industry has found it an excellent means of preventing the deterioration of roof and sides of slopes, entries, etc., by excluding mine air with its slacking effect. It also renders the surface fireproof, an important improvement in roadways carrying trolley wires or high tension conductors. These have been the source of many fires, and in some cases of explosions. On roadways where the weight is not excessive it can be used to give support to the roof, making a large saving by eliminating timber. Its use tends to make better

travelling and haulage roads for the same cause, as rock falling onto the rails is a frequent cause of derailments.

It is not to be expected that the use of gunite would be an economical means of supporting roadways in all mines, or indeed in all entries in any one mine; but where the cost of timber is high, and the strata driven through are practically self-supporting when first opened up, it might easily be justified. Certainly in all mines there are places where its use would be advisable, as in shaft and slope bottoms where timber is used more as a precaution than of necessity. Small falls that occur from time to time, causing the derailment of cars, or danger to men, would thus be avoided. The additional room obtained by the elimination of timber sets is another factor of importance in such places. The operator of any mine having the facilities to do so would be well advised to try the process on one or more of his development projects that come under the above category. If, as in some of the mines where it has been used, he found that after six years it was as good as when put in, he might find its use justifiable.

This article has mentioned only a few of the uses to which concrete can be put underground with profit and satisfaction to the operator. Others will suggest themselves to him from time to time as occasion arises. If he approaches the various projects with the thought and desire to have them permanent, he will frequently use concrete where in the past he has formerly used timber.

KIRKLAND LAKE PROPRIETARY DEVELOPMENTS

By ALEXANDER GRAY

Discussing the altered position underground at the Tough-Oakes properties of the Kirkland Lake Proprietary, the well-informed City Editor of *The African World*, at London, presents certain reflections on past errors of omission and commission while giving most encouraging details not as yet available to Canadians. The comment bestows upon Mr. H. S. Denny, Consulting Engineer and Vice-President of the new Tough-Oakes-Burnside operative company, the credit for having put an end to "happy-go-lucky methods" and the adoption of "a definite policy." Whoever did it, and replaced the Tough-Oakes in the middle of the road toward success, the semi-official acknowledgement is that the "ore did not keep pace with milling requirements," whereas the expectation now is that milling operations may be resumed in February, if not sooner. "Excursions" into ore of the grade indicated in the following, the "progressive policy" of Mr. Denny that has replaced the retrogressive policy as outlined, no doubt will be reflected in an increased output from the Kirkland Lake district.

"The Kirkland Lake Company is fostered by a group identified with South African and Rhodesian interests, and is being developed along lines laid down by Mr. H. S. Denny, the well-known consulting engineer, as famous on the Rand for his progressive policy, as he has become in the Canadian mining field. The Kirkland Lake property cannot be said to have been much of a success as a mining proposition until the services of Mr. Denny were requisitioned, since when the position has changed very materially for the better, and the outlook is now decidedly encouraging. It is not necessary to go into the history of the venture as it will be sufficient to say that, after a certain quantity of ore had been extracted, the ore reserves did not keep pace with the milling requirements, and the crushing plant was accordingly shut down, while attention was concentrated on underground development. The mining position was the existence of two shafts, and a good deal of driving the results of which, however, gave little payable tonnage.

"With Mr. Denny's advent the somewhat happy-go-lucky methods of underground work gave place to the carrying out of a definite policy, and the excursions into subsidiary formations were discouraged in favor of driving designed to locate what was considered the main lode. This Mr. Denny calculated should be intersected in certain positions, and the news now to hand confirms the accuracy of these anticipations. On the 7th level, a drive westward picked up indications of the main lode, and although the first 50 ft. gave poor results, since then the assays have been consistently good. After proceeding due west for some distance the lode swung to the south, and then returned to its original direction. The last cable stated that 40 feet driven averaged 34 dwts. over a width of 53 inches. This means that the lode where payable had been driven on altogether for 195 feet, and that the average value for the whole of that distance was 25 dwts. over 55 inches. Before the western boundary of the property is reached there is another 30 to 50 feet to be driven, so that it would be safe to assume that the lode on this level, on the western side of the diabase fault, will be well over 200 ft. of high-grade ore.

"With such an ore body there should be continuity both above and below the 7th level. On the 4th level some good ore was extracted some time ago. On the 5th level there were indications, but the level was driven straight westward, and probably missed the lode when it turned southward. The 6th level was not continued westward, but no doubt operations in that direction will presently be taken in hand, although at present the level is being used to explore the eastern section of the property. As the policy is to utilise diamond drilling to obtain information as to the character of the formation, it may be assumed that the continuance of the lode located on the 7th level will be proved in depth by such means. Owing to the strike of the diabase fault, southerly and easterly, the ore body may become of more importance at levels below the 7th.

"Turning to the prospects on the east of the diabase fault, where the bulk of the property lies, the 6th level, which was driven north and then east, has apparently just come into the lode, for a cable states that 14 ft. driven averages 8 1-2 dwts. over 64 inches, which indicates the entering of a good payable chute. The 7th level is also being driven eastward, and indications are reported to be decidedly encouraging. There is room in this direction for a long shoot of good grade ore.

"According to local information, a Canadian company has just been formed to take over the property. The capital of this corporation is $5,000,000, and the area acquired will be 420 acres. The present programme is to restart the mill in February, but it is not improbable that the excellent developments now being made may hasten the date, provided electric power is available. The terms which will be given to the shareholders of the present Kirkland Lake Company have not yet been made public, but it is understood they will be favourable. It is not the intention, I believe, to liquidate the present company, but to transform it from a mining concern into a holding company, while active mining operations will be conducted by the Canadian company, of which the vice-president will be Mr. H. S. Denny. This gentleman is certainly to be congratulated on the encouraging prospect of being able to add another success to those he has already secured.

Mineral Resources along Hudson Bay Railway and round Hudson Bay

Summary of Information by National Resources Intelligence Service

(Continued from page 823)

Gold

The first important mineral discovery in Northern Manitoba was the gold strike at Herb (Wekusko) lake in 1914. Since then many valuable properties have been partially financed and developed and many others examined. While gold is found throughout the mineralized area the most striking finds are reported from the eastern half at Herb lake, Little Herb lake and Elbow lake. Some of the Wekusko properties namely the Bingo, Rex, and Moosehorn mines were developed to a producing basis but the Bingo is the only mine at present actively operating. Very spectacular surface samples were obtained from Elbow lake but the persistence of values to depth has not yet been proven. Other claims have been staked on Pipestone and Little Playgreen lakes on the Nelson river and on Knee lake on the Hayes river and northwest of Amisk lake, Saskatchewan. The gold occurs in quartz veins carrying sulphide and is mined as a purely gold bearing rock or mixed with other metals.

Some pieces of vein-quartz picked up near the south side of Corbett inlet were found to carry a small amount of gold. Between Chesterfield inlet and Cape Fullerton there are several deposits of iron pyrites containing small amounts of gold. Free gold has been found in quartz at Repulse bay. Prospectors in 1912 reported placer gold on the banks of the Eastmain river. Gold is reported near Great Whale river and on the Ottawa islands.

Placer gold reported from Chipewyan lake, Churchill river, was investigated by the Geological Survey, but only meagre and isolated values were obtained.

Free gold is reported by Dr. Rae at the head of Wager inlet, west of Southampton island. There are large areas of dark basic rock carying sulphides in contact with the granite of that district which makes it a field of some promise for prospectors.

Graphite

Extensive veins of this material have been noticed in Ungava bay, also near Cape Wolstenholme and along the east side of Baffin land and some claims have been staked in the vicinity of Churchill.

Glass Sand

Quartz sand suitable for the manufacture of glass is exposed on the shores of Wapawekka lake, 150 miles northwest of The Pas.

Gypsum

Deposits of gypsum have been located on the Moose river between the Mattagami river and James bay.

Iron

Iron formations are known to exist over an extended area in the railway belt. Generally speaking they are sulphides occurring in association with Keewatin rocks and may be traced from Knee lake, one of the headwater bodies of the Hayes river, due west to Lac La Ronge in the province of Saskatchewan; occurrences, believed to be of commercial magnitude and purity, exist at various points along the Hudson bay shore line and especially on the islands of the east coast.

At Knee Lake the iron is present as a fine grained magnetite interstratified or interlaminated with schists. A sample tested about 45% iron free from titanic acid.

A loose specimen of interbanded jasper and hematite was found on the east shore of South Indian lake, Churchill river, and bog ores cover a wide area near Wapawekka lake, Saskatchewan.

Clay ironstone beds in the Pasquia hills show an iron content of 29.1%.

The Belcher islands, Hudson bay, possess formations of magnetite and hematite with which are associated iron silicate and carbonates. The formations outcrop as bands with highly ferruginous zones. Representative samples from these zones show an iron content of 35 to 45%. The high grade showings are for the most part interbedded with silicous material which would make for difficult mining operations. The ferruginous zones approximate an iron ore and more detailed examination of the field by trenching, test pits and diamond drilling might lead to the establishing of commercial bodies.

The Nastapoka group, composed of 44 islands off Richmond Gulf on the west coast, forms a valuable series of iron properties. Two of the islands are said to contain from 3 to 4 hundred million tons of the finest quality iron ore. The deposits are largely magnetite or a mixture of magnetite and hematite when associated with thin sandstone or jaspylite and siderite and ankerite where associated with the limestones. The ore beds average 7-15 feet in thickness but a depth of 80 feet of almost pure magnetite has been encountered. Manganese was present in most of the samples analysed. A large number of claims have been staked and granted. The islands are within 1-4 miles of the shore where shipping facilities and water power could be obtained.

The carbonate ores are found on the Nastapoka islands in the upper beds and on the Hopewell chain and on Long island, the greatest thickness noted being about 20 feet.

North of the Payne river, Ungava bay, there are iron-bearing beds 420 feet thick occurring as carbonates or a mixture of hematite and magnetite associated with chert and jasper. In places there are masses of pure iron but separation from the quartz would be necessary for commercial processes or quantities.

Bedded ores of low grade have also been examined in the south shores of Hudson Strait and siderite ores containing 35-47% on the Mattagami river, James bay, and a 35 % magnetite and hematite occurrence in sandstone beds, Sutton Mill lake district.

Lead

Lead is contained in the mixed ores of the Flin Flon mine and galena has been noted in small quantities at Herb (Wekusko) lake, Twin lake Athapapusko lake, in a dyke on the west side of Copper lake and at Wanipigon lake near Nelson House.

A deposit of galena carrying silver values in the Cambrian limestones in quantities sufficient to be of economic importance was traced for 12 miles from Little Whale River to Richmond Gulf, Hudson Bay. Assays gave 5.04 - 12.03 oz. silver per ton. The Hudson Bay

Company mined a lead property at the Little Whale river at one time, but workings were later abandoned.

Manganese

Important deposits of spathic iron containing manganese exist on the Nastapoka islands. A sample from Flint island showed 25.44% metallic iron and over 24% carbonate of manganese. These deposits are accessible and of promise commercially. They might be used in the manufacture of spiegeleisen.

Mica

Mica occurring in large plates of green muscovite in massive pegmatite dykes, has been observed between Talking and Island falls on the East Main river.

A Scotch whaler took out 13 tons of excellent mica from a mine at Lake Harbor, Hudson strait, in 1903.

Prospectors have also registered some claims near Churchill and a small sample was obtained from an island in Cross Lake, Nelson river.

Molybdenum

At the south end of Phantom lake in the Flin Flon area a quartz vein near the granite contact, containing pyrite, chalcopyrite and considerable molybdenite was traced for 100 feet with an average width of 3 feet. Other evidences of molybdenite have been obtained in the vicinity as well as at the Dominion claims, Brunne lake, where it occurs as flakes in fissures of the quartz, on the shores of Little Playgreen lake near the exit of the Nelson river from lake Winnipeg where the occurrence takes the form of round crystal aggregates in red pegmatite, on the Echimamish river at a contact between gneiss and intrusive rocks, on the west bank of the Grass river near Wekusko (Herb) lake, on the Eastmain coast, Hudson Bay, and as plates in syenite dykes on the Paint Hill Islands, James Bay.

Nickel

Near mile 196, Hudson Bay railway, contact of greenstone and gneiss shows mineralization of magnetite, pyrrhotite and chalcopyrite with low values in gold and nickel. Pyrite and pyrrhotite containing slight quantities of gold, silver and nickel are noted on Webb creek north of Elbow lake. These claims were only imperfectly prospected owing to the swampy nature of the district, but values obtained were not encouraging. Nickel associated with pyrites is stated to occur in veins at Camping island, 10 miles south of Priest's Point, Reindeer lake, Saskatchewan.

Oil Shales

Oil shales 150 feet thick are exposed on the Carrot river and on the northern and eastern slopes of the Pasquia hills. The beds are horizontal and would appear to underlie the entire range. Samples from surface exposures analysed 7 gallons crude oil and 20 pounds of ammonium sulphate per ton but do not of necessity represent the richest beds. The Federal Department of Mines is investigating the problem of extraction of oil from such shales. Some drilling for oil was done in 1921 near the junction of the Carrot and Man rivers.

Pigments

Mineral springs depositing ochres and numbers which might be utilized in paint manufacturing are found 150 miles northwest of The Pas at Wapawekka lake. Red ochre in small quantities but of good quality has been found on Cross lake, Saskatchewan river. Several claims are staked.

Peat

Formations of peat are widely distributed over the entire railway belt although ground ice such as is found in the more northern swamps tends to retard their formation. Amongst the bogs of commercial possibilities might be mentioned (1î north of Grand rapids, Saskatchewan river (2) between Grass river and Beaverhouse lake on Burntwood river (3) Little Churchill river near Switching river (4) on creek north of H.B. post at Split lake (5) both sides of south part of Waskaiowaka lake (6) outlet of Assean lake (7) 21 miles below the forks, Churchill river (8) Lagoons 12 miles south of Recluse lake (9) between Deer lake and Churchill river (10)northwest side of Swampy lake below Knee lake. Hayes river (11) near Clearwater lake. Mink river (12 near Swampy Portage lake between Knee and God's lakes.

Platinum

Platinum values have been obtained on the Caribou claims, west side of Brunne lake, and on claims north of Cranberry lake and near Wekusko (Herb) lake. They are not commercial deposits in themselves.

Quicksilver

Dr. Alexander Brown, surgeon at Churchill, gave evidence before a British parliamentary enquiry in 1748 that a red eaarth, obtained 36 miles south of the Churchill river, reacted like cinnabar, the ore of quicksilver.

Salt

A series of natural salt springs extends from the Carrot River valley southeast along the west side of Lake Winnipegosis and beyond. At one time crude evaporation methods were employed to obtain salt for local purposes but at present none is obtained locally.

Silver

Silver occurs in The Pas mineral belt and is recovered in connection witnh the gold and copper ores, a total of 15,510 ounces having been produced in 1920, since when production has ceased. The gold-silver-copper camps are Schist lake, Athapapuskow lake, Flin Flon lake, river, Copper and Brunne lakes. The silver content of the Flin Flon 16,000,000-ton ore body is estimated at 1.17 ounces per ton, while the treated ore from the Mandy mine showed 2½ ounces per ton.

Silver-lead ores are also reported from Pukkatawagan or Cold lake, from northeast of Herb lake, from the Copper and Brunne Lake district, and from Wanipigon lake north of Nelson House. Segregated pyrite in the squeezed trap of the Paint Hill area carry small silver values. Galena showing silver values of 5.04 - 12.00 ounces per ton from samples has been traced for 12 miles from Little Whale river to Richmond Gulf.

Sulphur

The presence of large and widespread iron and copper sulphide bodies at various points in the Keewatin belts suggests a possible source of sulphuric acid or sulphur. Among the sulphides found in the railway belt, on the Churchill river and along the coast are iron pyrites, chalcopyrite, bornite, arsenopyrite, sphalerite (zinc blende) stibnite (sulphide of antimony) and pyrrhotite.

Many of the properties on Ross lake, northeast of Schist lake, on the Pineroot river, at the north end of lake Athapapuskow, and on Brunne and Copper lakes show characteristic occurrences of iron pyrites in extensive zones and bands, associated in part with copper values, in origin similar to the Flin Flon and Mandy ore bodies.

Iron pyrites appear in the limestones of Long island, on the Eastmain river and on the islands north of Cape

Jones, and in the Paint Hill group; the vicinity of Mosquito bay, north of Portland Promontory appears to be an area favourable to these sulphides. Pyrites has also been noted on the west coast near Corbett inlet in Mistake bay and other places.

Talc

Soapstone obtained near Mosquito bay is used by the Eskimos of the East coast for making utensils. A possible source of material for fire clay is found in the pipestone from Wapawekka lake, Saskatchewan, 150 miles northwest of The Pas

Zinc

Zinc is associated as sphalerite with the copper sulphide ores of The Pas mineral belt, the Flin Flon mine showing an average zinc content of 3½% while the ore of the Mandy mine runs about 20% zinc. It is also associated with calcspar in veins south of Little Whale river and as crystals in galena on this part of the coast.

PROSPECTOR, GEOLOGIST, AND ENGINEER

During a discussion of present-day prospecting at an A. I. M. M. E. meeting in San Francisco last year, Dr. Andrew C. Lawson, formerly of the Canadian Geological Survey and now professor of geology at Leland Stanford, contributed the following pertinent remarks:

"In recent years geology is becoming recognized as the means to the finding of ore. Only a limited number of people can be good geologists. We can train men, but unless they have an aptitude for that work, they do not make really good geologists. If we train a man in the technique of geology, he will be useful to the mining industry in the finding of orebodies, provided that the people who want orebodies are willing to pay for his services; that condition does not exist at the present time. People willing to employ a good geologist today not only must pay him an attractive salary, but they must not expect that every time he makes a trial he will be successful. There will be a large percentage of failures. We should do our best to make the prospector a good geologist, and make the work of looking for mines attractive to him. The oil men are employing geologists. It is hard to keep students at Berkeley because of the large salaries paid by the oil people; and because of this the country is flooded with boys who call themselves experts. More than three-quarters of the boys are incompetent to do their work, but they have the confidence of boards of directors. The country is full of such men who in time will not make a good livelihood out of their geological work; their training is too narrow. The only way to get a man to meet the various conditions that would be encountered in looking for a mine is to make of him a good geologist."

On the same occasion Professor J. C. Jones of Mackay School of Mines had this to say of the prospector:

"The old-time prospectors went out and searched for mines. They had no particular school training, but they were among the keenest of observers and learned their geology by experience; that is, in the mines. When they were confronted by a set of conditions they looked into them. If anything went wrong in one place, they moved to another; and each time they made a mistake they learned something until they became quite fair geologists. They might not have called rocks by the names we do, but they had the knowledge necessary to find the mines. While a sound training in geology is of great value, there are limitations to the science. In civil engineering, for instance, the engineer is used to dealing with exact mathematical facts; the geologist is not. He is at times confronted with certain elements of uncertainty even when facts have been fairly well established; for instance, when it comes to foretelling the value of the ore that one is going to find, or deciding whether or not there is any ore.

"Every January, at the Mackay School of Mines we have a four-weeks' course, known as the prospector's short course. In that course, the prospectors get a series of lectures in which sufficient detail work is given so that they have an inkling of our present ideas. They get a little geology and mineralogy, a little first aid and hygiene, a little mining law, surveying, gas-engine work, assaying and chemistry, and while at the end of that time they are not college graduates, they have learned something which, when applied to their own observations, proves to be of great help to them."

In discussing the relation of the large mining coporation to the prospector, Mr. P. G. Spilsbury, of Phoenix, Arizona, said, in part:

"We have been trying to encourage the prospectors by giving them facts. We will go out with any man who has a reasonable proposition, and if his property is worthless, we try to show him why. We spend much time trying to show prospectors, who are on worthless ground, why they cannot make a mine. We have, in this way, been able to do some good. Furteen or fifteen of these men come into our office regularly for advice. They bring in their propositions and we talk them over, not with the idea that we will buy them, but that we are there to help them. We do not give any course in geology, but our geologist explains to them, if necessary, what the requirements are for success. We help these men a little financially. We get much information about districts that could not be secured in any other way, and I believe this is one of the methods by which we can work with the prospector. We cannot make him highly educated as he has not the basis; but if we can secure his confidence, give him a square deal, and try to show him where he can do his best, we can encourage his work and possibly get results from it.

"When a prospector brings in information regarding his property, we first determine if there is a faint possibility of its being of interest. If we decide affirmatively, we send out our field man to make a preliminary examination. This man is a very good observer and brings his information to the office. This is considered by my geologist and myself. If worthless, we determine why and drop it. If there is a possibility of making a mine out of it, the geologist makes another examination. If his word is unfavorable, we drop the proposition giving, in our report, the full reasons for our decision. If his report is favorable, my field man, geologist, and I visit the property and go over it thoroughly. The final report therefore is the opinion of a prospector, a geologist, and a business man. If the property proves hopeless, we always tell the owner why we consider it so and give him the benefit of our information.

"Only about 60 per cent. of the prospectors whose properties we decide are worthless take the explanation in the right spirit. The prospectors who are getting to know us are gradually realizing that it is our job to help them and that in this way we will gain results. We believe in the work of the prospector and we are giving him all the help and encouragement possible."

POLYTECHNIC AT ANYOX

Classes in a wide variety of subjects, from English to Metallurgy, have been inaugurated in Anyox, B. C., under the wing of the Northern British Columbia Polytechnic Institute. The Granby Company and the local technical staff are backing the new school.

The Coal Trade of America and Europe

By ALEXANDER V. DYE, in Commerce Reports

Th only practical sources of power on a commercial scale are coal, petroleum, natural gas, and water, and a recent comparison made by a German statistician shows that of the 177,600,000 horsepower obtained from these sources in 1919 coal furnished 160,600,000. From this it will be seen that in spite of the recent increase in the use of petroleum, coal still remains the dominant driving force of the world.

Another reason why coal should interest the average business man is because about 90 per cent of the world's coal comes, from only two areas which, while large in themselves, are very small compared to the total surface of the earth. One of these areas embraces the coal fields of the eastern part of the United States and the other includes Great Britain, Germany, Belgium, and northern France. Likewise the greater portion of the world's commerce moves to and from these two areas or back and forth within them.

Relative Production of Europe and America

The European area supplies about 50 per cent of the world's coal and about 40 per cent comes from the United States fields, although these proportions are rapidly changing. The coal trade was developed much earlier in the European area as an integral part of the development of steam power and manufactures. In fact, as late as 1860 Great Britain alone produced four-fifths of the world's coal and while British output increased steadily until in 1913 it reached its peak with a production of 287,000,000 tons, its proportion of the world's production sank steadily from 80 per cent in 1860 to 21 per cent in 1913. This relative decrease in the development and control of the driving power of the world was principally due to the economic rise and development of the United States and Germany, with the coal development of France, Belgium, Austria, and the rest of the world as contributing factors.

Side by side with this change in proportion of total output, there has been a steady decline in the output per man in Europe and an increase in the output per man in the United States. At the present time, generally speaking, one coal worker in the United States produces about three times as much coal in the year as a European worker. This is due to man reasons among which may be stated that, in the first place, the coal seams in America are closer to the earth's surface and are flatter and thicker. In Europe many small shafts were sunk and narrow haulage ways driven before experience had shown the economy of mining operations on a large scale with large shafts and wide haulage ways. Labor-saving machinery is used to a far greater extent in America, about 60 per cent of American coal being mined by machinery and only about 15 per cent of European coal. However, in addition to all these factors it seems probable that the American miner actually works harder.

Results of Shorter Working-Day

After the war coal was scarce in Europe, but the coal miners in European countries cut their working-day from eight to seven hours just at the time when coal was needed most to start driving again the wheels of commerce. The consequence has been that a steadily increasing number of men had to be employed to produce the same amount of coal. In England the production of coal per man per day averages about 0.9 ton; in Germany it is about 0.6 ton, and in France and Belgium slightly more.

This means higher overhead costs, as water constantly trickles into the mine workings and must be pumped out, the underground pressure cracks timbers which must be replaced, and the earth loosens and falls into the workings. Thus before the war, in England, for every 1,000 men who were actually digging coal at the face about 1,100 men were doing the other necessary work about the mine. Now, since the hours of all workers have been reduced, for every 1,000 men digging coal it takes 1,500 to do the other work. As a result it takes more people to do the coal mining for the country. The output of coal in Great Britain was almost exactly the same in 1922 (252,000,000 tons) as in 1906, but in 1922, 1,100,000 men were employed to mine it as against 875,000 in 1906. On the other hand each worker receives about 45 per cent more wages than he did in 1913, so that with the decreased output the price of coal must remain high.

Earnings of British Miners

In Great Britain during the first quarter of 1923, 1,087,733 workers in the coal mines produced 67,077,543 tons of saleable coal which sold for £58,156,716, or at the current rate of exchange $267,518,409, a little less than $4 a ton. Judging by the figures for the first quarter, each of these million-odd workers will be employed 280 days during the present year and produce 252 tons of coal worth about $1,000. If this year's production is worth only $1,000 it is obvious that his wages would be considerably lower than this amount. As a matter of fact each worker received on an average $2.22 per day (at current rates of exchange) and although his wages will probably be higher during the remainder of the year it is safe to say his year's income will not exceed $700.

In Germany, France, and Belguim the situation is much the same. The small output per man makes the price of coal high for manufacturing purposes so that Europe can not sell cheaply enough to dispose of its goods and thus obtain money to buy more American raw material. The result is that commerce is slowed down at the start.

Future Outlook

In the meantime the British coal trade carries on and it will always meet American competition, because it must, in the markets that are necessary, particularly those of northern Europe. Coal forms 80 per cent in weight and 10 per cent in value of all outbound cargoes from Great Britain. About 30 per cent of all coal mined in England is exported either as ships' bunkers or cargo coal. This export is vital to British economic life and will be maintained under any circumstances.

It seems probable that American coal exports will become entrenched in the south of Europe and take some markets formerly considered as British preserves, provided the price and transportation facilities are favorable. A number of large British coal exporters, seeing the trend of trade, are opening offices in New York in order that they may be in a position to handle American coaling markets where they can not sell the British product.

Technically Directed Prospecting

Augustus Locke Advocates Adopting Scientific Method in the Search for Ore

In a paper issued with *Mining and Metallurgy* for August, 1923, Augustus Locke of San Francisco discusses "Present Tendencies in Exploration for New Mines". As much that he says is pertinent to exploration in both eastern and western Canada, the second part of the paper is presented here, in abstract. Especially does Mr. Locke dwell on one point that has been emphasized on numerous occasions by the *Canadian Mining Journal* — that trained mining engineers should and will take hold of prospecting in the near future as they have taken hold of mining operations in the recent past, and so organize and direct the search for new ore-bodies that the chances of finding them will be much enhanced. Mr. Locke says, in part:

Stages of Prospecting

Ore discovery in western North America falls into three periods: first, the discovery of great, new districts — a feature of the advancing frontier; second, the discovery of new mines in old districts; third, the discovery of new ore in old mines, near known ore. The United States is now in the third period. Are the new mines, then, like the new lands, all taken? We cannot accept this conclusion without close examination. It may be there are many new mines awaiting the advent of a finer ore-hunting art.

There are many kinds of hidden ore. Much lies covered by drift and, in Canada, by moss and water. In arid districts such ore is sometimes visible at the edge of the drift, but in forested areas the cover is more continuous and the search more baffling. Geological knowledge, aided by small drilling outfits, will improve present methods. The study of physiography, too, will help, and we must not neglect the possibility of aid from electrical devices.

Concealed Outcrops of Ore

Bulky, conspicuous croppings, with iron and copper stain, have been the copper hunter's favorite; they lie broadside to the sky. We shall find few new mines by this means. If, however, the ore is especially high in pyrite or low in neutralizer (such as calcite or feldspar) the evidence of copper may be obscured. If, again, the ore is low in iron or lies in a forested country where organic acids can dissolve the limonite from the surface, the cropping may even be further obscured.

Irregular garnet-limestone ore deposits, which have croppings of high-grade shipping ore that soon pinch out, attract the prospector but repel the engineer, and have given certain districts a bad reputation. Yet alongside these may lie rich limestone ore that weathers easily and is covered. The garnet croppings may indicate hidden riches.

Some sulphide deposits, such as that of Kyshtein in Russia, may weather to a sand, which is easily passed over by the prospector.

In general, small, rich ore-bodies seem more liable to discovery in the future than large,low-grade ones. Steep-dipping bodies like the United Verde remain undiscovered longer than flat-lying deposits such as those of Miami. Rich, secondary ore near the surface is found more easily than the deep, primary deposits. Veins will be found in the future oftener than massive deposits, for veins may appear on the surface as thin discontinuous lines, and may lie with their big ends buried in the rocks. Butte is an illustration, the veins there have been discovered less on the surface than underground, and the surface is in sharp contrast to Miami, whose red hills show up miles away.

Hidden and Unusual Ore Bodies

Deposits that fail to outcrop, such as those in flat beds or flat-lying fractures; veins that are barren at the surface but whose geological associations and grade of ore improve underground; deep-lying ore terminated by a fault near the surface; these in some measure are saved for the future. Other deposits may be overlooked temporarily because of more spectacular outcrops near them; if these latter fail to make good, then those of poorer appearance are condemned, though they may really be of better grade.

Deposits of unusual types, of which no example has been recorded on this continent, may go long unheeded. In other cases the usual guides may be missing. Thus, though the prospector usually traces and locates a gold deposit through its local placers, glaciation may have removed this guide. Silver deposits, such as those of Tonopah or Pachwea, may be hidden by a cap of later, barren rock, to be discovered only by some lucky chance, or perhaps by means of some future scientific aid to prospecting.

Ore bodies to whose origin no definite cause can be assigned, that is those to which no specific guides are known, compose a large class. In the past the search for such deposits, especially in new districts, has been without logic technical aid, and mere physical energy has been the prospector's chief stock-in-trade. It seems certain that progress in the study of ore-deposits and of geology in general will provide some guides to these occurrences, which will convert the prospectors' work from a blind to a logical search.

Condemned Prospects

Then these are prospects that have been condemned on the strength of a little underground work. A few unlucky drill-holes may prejudice the engineer against a hundred acres of mineralized ground. Unless these holes are so placed as to be typical of the whole section, little real information has been gained. Many deposits that later have made mines have been thus condemned, and more await the further investigation that will turn failure into success.

Many more examples such as these could be cited. It is typical of them that they are valuable ore-deposits that lie unseen by the multitude and have been passed over by the pioneer prospector. Their discovery will be the result of careful and logical search.

The Examining Engineer of Today

What is the present practice? It is not, in general, a careful and logical search. The average prospector works much as he has always done, though with less spirit than formerly. We who act as examining engineers are only better educated and less patient pros-

pectors; we are better business men and can express an opinion more plainly, but we, too, are hoping, like the prospector, to come at last, through mere physical activity, to the happy valley where obvious signs of ore will lie before our eyes. This is a false hope. The prospecting of the future must include more than physical energy and financial competency. It must involve a study of questions now avoided, a collecting of all available evidence in advance of actual exploration and the expulsion from one's mind of all unreasoning prejudice, one way or the other. It must be so thorough that no chance for ore which is, in the mining sense, a good speculation, is lost through mental apathy, shallow thinking or hurry.

Prospector of the Future

This scheme for the future will involve a radical departure from present practice. How can it be brought about? It can be effected only by the man of science. He is as necessary here as in the chemical industries. To some small extent he is already in the prospecting business, chiefly as a geologist with a purely scientific object in view. Nevertheless there is evidence that the study of ore-deposits is being applied actively in the search of the prospector to a small extent. Certain men who direct exploration are commencing to realize the advisability of employing the best technicians they can find. They realize that the discovery of a given prospect is not merely an isolated event, but is part of a larger problem. They are likely, in time, to give their full support to schemes of action involving this larger problem.

The search for new mines will become a studied, deliberative affair. Not much longer will it be considered good practice to allow scouts to examine prospects, so many in a month, in separated districts. These scouts will be instructed to conduct their examinations, not so much prospect by prospect as district by district. Under certain conditions they will subject particular districts to long and careful study.

The technical control of exploration seems be on the way. Its usefulness is questioned by the man on the street, chiefly because ore discovery is at best a speculative affair. But there is a difference between one chance in fifty and ore in a hundred, though both are speculative. Technically directed prospecting promises, before the lapse of twenty years, a reduction of the speculative risk in something like this proportion.

AMMONIA LEACHING IN CHILE

If industrial tests to be made soon on a large scale confirm eminently successful laboratory experiments, and prove the claims made for a purely chemical process to reduce copper ore devised by a Chilean, Dr. Eduardo Solovera, copper production from low-grade ores will be revolutionized, and Chile will probably become not only the largest copper-producing country in the world but also a very large producer of aluminium and gypsum as by-products.

The advantages claimed for the Solovera process are that it requires only a fraction of the investment needed by electrolytic methods, and that the average production costs, under Chilean conditions, will be reduced from $200 to $70 a ton of metallic copper. This production cost will be greatly lowered, and in favourable cases more than completely covered, by the sale of by-products.

The process involves leaching the ore, when necessary, with dilute sulphuric acid (some Chilean copper ores, including that at Chuquicamata, are self-leaching and do not require the use of acid), which results in instantaneous precipitation of basic salts of copper by means of ammonium hydrate; a recuperation of the reagent (ammonia) follows, together with the production of calcium sulphate (gypsum) and aluminium oxide, both lime and alumina being part of the composition of Chilean copper ores, the "Teniente" ore mineral containing 20 per cent. of the latter.

In the tests the copper hydroxide precipitate, which may easily be reduced by known methods, has never been of less than 65 per cent. and it has often reached the theoretical maximum of 80 per cent. metallic content.

The use of ammonia in the reduction of copper compounds is current in laboratory practice, but, because of its high price, it has never been available in the industrial production of copper. The essential value of the Solovera process is that it permits the integral recuperation of the ammonia at a very nominal cost, and that in the course of the operation valuable by-products—aluminium oxide and gypsum—are produced.

Some years ago the Chilean Government endeavoured to break the Guggenheim-Anaconda monopoly by attacking the validity of its electrolytic patents in the Chilean Courts for reasons of public interests, but failed, and thus the combine was able to practically eliminate competition by independent concerns, and hence to restrict production in a way which Chileans consider detrimental to their interests.

The Nitrates & Mining School of Antofagasta, the Chilean Institute of Mining Engineers, and the Scientific Association of Chile, under whose auspices tests of the process have been made, have urged the Chilean Government to take steps to prevent the patents from falling into the hands of the copper combine, so that they may remain available for the creation of a Chilean copper industry independent of foreign control.—*The Mining Journal.*

PERSONAL AND GENERAL

Mr. D. H. MacDougall has been appointed consulting engineer to the McIntyre Mines, who own coal mines in Alberta.

Mr. D. T. Burns, of the Koppers Company, of Pittsburgh, is in Sydney to oversee the initial heating of the new battery of the Koppers by-product coke ovens.

Dr. E. L. Bruce made a geologist survey for the Ontario Department of Mines during the past season in the Red Lake area, not far from the Manitoba boundary. The reputed silver discovery consists of a narrow vein containing galena, which carries low values in silver. A party of prospectors from the Cobalt district went to Red Lake last spring, on the strength of the reported find. They determined at once that the reports were without foundation, but proceeded to spend the season in general prospecting. The result is that they have found a number of narrow gold-bearing quartz veins in a geological association identical with that of Porcupine. Temiskaming sediments and rocks of Keewatin age are cut by syenite and porphyry, and are enclosed in the granite batholith. Dr. Bruce has mapped an area 30 miles by 10 miles, which will be an adequate preparation for detailed prospecting if the area should prove to be of importance.

On Friday of last week Dr. W. L. Goodwin was presented by his former students with a protrait of himself, painted by Mr G. Horne Russell, the occasion being the fall convocation of Queen's University, Kingston.

SHORTAGE OF LABOR ON THE RAND

During August 769,371 ounces of fine gold were produced by the mines of the Transvaal, an increase of 15,065 ounces over the July output. Priced at 88s. an ounce, an increase of 4d. over the preceding month, valuation of gold was officially declared at £3,385,232. as against £3,300,088 for July. Working costs in the mines are being further reduced.

Increasing shortage of native labor in the Rand has lowered the production of several mines—the Crown Mines, which have the largest output on the Rand, and the Simmer and Jack Mine finding it necessary to close down over week ends. A slight improvement was noted in native labor, 167,600 being employed in the gold mines at the end of August, an increase of 1,167 over July. More Portuguese natives are being recruited, but the mines are still short some 15,000 workers of this class.

The failure to obtain sufficient natives has adversely affected the employment of whites, not only in the mines but in certain other industries. Premier Smuts recently announced that the Government was spending £16,000,000 on reproductive works, such as railway construction and afforestation, for the relief of white unemployment. Although wages of 9s. to 10s. a day are offered, it has been difficult to induce men to leave the towns for the country, necessitating the employment of natives. — Commerce Reports.

FINAL STATISTICS, 1922, ON PETROLEUM AND NON-METALLICS

The Dominion Bureau of Statistics has issued the following finally revised statistics on the production of crude petroleum and miscellaneous non-metallic minerals in Canada during 1922, under date of October 10th.

Petroleum

The production of crude petroleum in Canada in 1922 amounted to 179,068 barrels having a sales value of $520,073. Government bounties on these sales amounted to $91,103 making the total value $611,176 to the producers. In 1921, the production was 187,541 barrels having a total value of $641,533. The average market value per barrels, in 1922was $2.90 while in 1921 it was $2.92.

Crude Petroleum in Canada, by Fields, 1922

Field	Quantity in Barrels Tons	Value less Bounty $	Bounty Paid $	Total Value $
New Brunswick	7,778	28,359	4,373	32,732
Ontario:				
Petrolia & Enniskillen	64,935	173,375	34,091	217,466
Oil Springs	43,214	115,380	22,687	138,067
Moore Township	7,275	19,424	3,819	23,243
Sarnia Township	3,224	8,607	1,692	10,299
Plympton Township	695	1,856	365	2,221
Bothwell	25,681	68,568	13,482	82,050
Tilbury East	127	338	67	405
West Dover	5,482	14,638	2,878	17,516
Raleigh Township	663	1,771	348	2,119

Total for Canada	179,068	520,073	91,103	611,176

Miscellaneous Non-Metallic Minerals

The Dominion Bureau of Statistics issues the following finally revised statistics on the production of Non-Metallic Minerals in Canada during 1922.

With the exception of arsenic there were no outstanding differences between the production of 1922 and the previous year of the commodities listed in the table below as miscellaneous non-metallic minerals.

The production of arsenic in 1922 was 2,576 tons, an increase of 1,085 tons or 42% when compared with 1921. Large quantities of this commodity are being used in the United States for insecticides which are found to be particularly effective in combating the boll weevil, an insect which has caused great damage in the cotton districts during recent years.

		1922	
		Quantity	Value
Actinolite	Tons	50	575 $
Arsenic (white) produced from Canadian ores	Tons	2,576	321,037
Barytes	Tons	289	9,537
Chromite	Tons	767	11,503
Feldspar	Tons	27,727	248,402
Fluorspar	Tons	4,505	102,138
Graphite	Tons	597	31,353
Grindstones	Tons	1,005	43,742
Magnesite	Tons	2,849	76,294
Magnesium sulphate	Tons	1,021	24,017
Manganese	Tons	73	2,044
Mica	Tons	3,349	152,263
Mineral water	Gals	221,433	14,220
Natro-Alunite	Tons	50	2,500
Iron oxides	Tons	7,285	110,608
Peat	Tons	3,000	14,500
Phosphate	Tons	190	1,796
Pyrites	Tons	18,143	74,303
Quartz	Tons	109,947	208,598
Sodium carbonate	Tons	202	3,027
Sodium sulphate	Tons	504	11,980
Talc	Tons	13,195	188,458
Tripolite	Tons	219	5,781
TOTAL			1,658,676

EARNING POWER OF RESEARCH

Originally, the lead from which cable sheaths are made was given a 3 per cent admixture of tin to obtain the necessary mechanical properties in the alloy. About twelve years ago the price of tin advanced, while the increase in the quantity required for new telephone cable construction became so large that research was called upon to provide a substitute. As a result new sheaths contain one per cent of antimony and in ten years the new formula has earned a saving approximating $6,000,000.

Another important metallurgical result was an improved contact metal used in the millions of relays and tiny switches required in telephone plants and central stations. Since 1916 this new metal has earned through savings about $13,000,000.

Another illustration of the earning power of research taken from the experience of the Bell system is the use of so-called phantom circuits. A simple circuit consists of two line wires. In phantoming it is possible to superimpose a third circuit upon two pairs of such wires, utilizing each pair as if it were a single line wire. At present there are about 400,000 miles of phantom circuit in the Bell system. The cost involved in obtaining these phantom circuits was about $9,000,000, but the cost of the additional copper wire necessary to string simple circuits to do this work would have been $90,000,000.

These earnings are real and the income upon the investment in research which makes them possible is greater than that usually obtained in commercial ventures.—

Industrial and Engineering Chemistry.

NEW GEOLOGICAL SURVEY INDEX

The Geological Survey has just issued an *Index to Separate Reports,* 1906,-1910, *and Summary Reports,* 1905-1916, by F. J. Nicolas. In 1908 the Survey issued a general index to reports up to 1904. There was, at that time, a half-promise that the index would be brought up to date every ten years. The 1908 index was commended highly by this and other journals; but the London *Times* remarked that the number of pages indexed was scarcely 13,000 and the pages in the index amounted to over 1,000—an undue proportion of references. The present index covers about 10,000 pages, from 1905 to 1916, and consists of 300 pages—a much more reasonable proportion. In 1910 the series of separate reports was terminated, to be carried on as monographs, thus accounting for the apparent inconsistency in the dates shown in the title.

The work has been compiled, evidently, with great skill and care and by one with a thorough knowledge of the art of indexing—an art so little understood by the average writer, but so much appreciated by readers. The author, in his preface, acknowledges the constant and willing aid of his confrères of the Geological Survey, who must therefore share in the congratulations due for this excellent piece of work.

The present index does not include the memoirs (the Survey's chief record) or the bulletins. There remains, therefore, to be prepared an index that will cover the whole of the Survey's recorded accomplishments up to a recent date. One may hope, on behalf of the geologists and mining engineers who will make good use of such a work that it also may be compiled by the author of the present index.

NEW SOAPSTONE DEPOSIT

A new deposit of soapstone has been discovered on Trap Lake, a small lake south of Wabigoon lake, in northwestern Ontario. The quality of the stone has been reported as excellent for various industrial uses, and practical trials are under way. Water transportation is available direct from the deposits to Wabigoon and Dryden on the main line of the Canadian Pacific Railway.

USES OF ARSENIC

During 1922 about 8,000 tons of calcium arsenate was distributed to cotton growers in the Southern States to help fight the boll weevil. It was first used for that purpose in 1919. Lead arsenate is the chief arsenic compound used; during 1922 about five times as much was used in the United States as all other arsenical compounds combined, including calcium arsenate, Paris green and Bordeaux mixture. Of this the manufacture of plate glass consumed 1,500 tons. The manufacture of weed killers, sheep dips and numerous minor uses consumes smaller quantities annually.

OCHRE IN WALES

It is reported that important deposits of ochre have been discovered in Wales, which it is expected will go a long way towards making British manufacturers of paints, linoleum, etc. independent of imported ochre.

The weight of the petroleum imported into Great Britain in 1922 exceeded that of any other raw material; iron ore ranked second.

SOME NOTES ON MINING IN EUROPE

Remarkable progress has been achieved in the reconstruction of the French mining industry, systematically destroyed in war-time by the invading Germans, according to George S. Rice, chief mining engineer of the United States Bureau of Mines. Mr. Rice has just returned after completing a study, occupying several months, of conditions in the mining industries of France, Great Britain, Belgium, Germany, Poland, and Czechoslovakia. As a result of the splendid engineering skill employed in the restoration work, some of the finest coal-mining plants in the world have been constructed in the north of France, states Mr. Rice in a report made to Director H. Foster Bain of the Bureau of Mines. Thousands of miners' houses have been built, replacing those destroyed. These houses are quite attractive and most of them have gardens, which have been redeemed from trenched and blasted ground. Much attention has been paid to welfare projects, with the result that the miners of northern France are undoubtedly better housed than miners in any other part of the world. Underground, the mines have been recovered to such an extent that they are producing about 70 per cent. of the normal coal output. When all the water has been pumped out of the mines, the coal production of northern France will be greatly increased over that of the pre-war period. Ingenious cementation methods have been employed in the restoration of mine shafts in which the iron linings had been destroyed, thus flooding the mines.

Mining Petroleum Sands

Novel methods for obtaining petroleum, involving the mining of oil sands and their subsequent treatment at the surface, were observed by Mr. Rice in Alsace and near Hanover. This makes possible a greater recovery of the petroleum, two-thirds of which, it is estimated, is left in the ground after ordinary extraction by wells.

In England, Mr. Rice had the opportunity of observing the experiments directed by Oxford and Birmingham Universities regarding the health and working capacity of miners employed in excessively hot mines. As the result of the researches of Dr. J. S. Haldane, eminent mine physiologist, it has been found that miners working in hot atmospheres lose chlorides rapidly, which is very weakening. The energy of the workers, it has been found, can to a great extent be re-established by the taking of salt in water, or some other liquid.

Profit-Sharing in English Collieries

An interesting sociological development in the coal-mining industry of Great Britain, whereby the mine owners and the miners share in the distribution of profits, was studied by Mr. Rice. Under this plan, the mines are grouped in certain districts and monthly, in each designated district, the gross total expenses of production of the coal are deducted from the gross profits of the mines of that district and from this gross net profit there is deducted 6 per cent of the invested capital; the remainder, if any is divided between the owners and miners, the owners receiving 17 1-2 per cent and the miners 82 1-2 per cent. The miners' share, if any, is pro-rated among the miners of the district and the amount thus determined by certified accountants is paid to the miners two months later in the form of an increase in wages.

Interesting developments in the problem of surface subsidence resulting from mining operations were observed in Great Britain and France. At St. Etienne, France, mines have passed under important buildings which have been sunk as much as 20 feet without material damage, because of the careful packing methods em-

ployed. The mine subsidence problem is one of growing seriousness in various European countries. The British Parliament has recently established a commission to study the situation, with a view to recommending special remedial legislation.

Stone Dusting Compulsory

In Great Britain and France, the employment of rock dust as a screen or barrier for the limitation of coal dust explosions to the immediate area of the explosion has been made compulsory. The efficacy of this method was strikingly demonstrated in the case of a gas explosion in a Yorkshire colliery where the stone dusting confined the explosion to its immediate place of origin and prevented the great loss of life that must have occurred had the explosion spread through the mine. Much experimental work along this line has been performed in the United States by the Bueau of Mines, Mr. Rice points out, but the States have as yet enacted no legislation to compel the adoption of this system in the mines of the country.

Liquid Oxygen Explosive

Liquid oxygen explosives are being extensively used in France and Germany in metal mining and quarrying operations. This type of explosive is not, however, being employed in coal mines because of the assumed danger of causing coal dust explosions. Tests employing liquid oxygen explosives in quarries and metal mines in the United States are now being made by the Bureau of Mines at Pittsburgh, Pa., and at other field stations.

Advances in Coal Technology

Mr. Rice found that research into the causes and prevention of mine explosions had been virtually stopped in Europe during the war-time period and had not been fully resumed in continental countries except that in France the fundamentals of safety explosives are being studied. In Great Britain, research along this line has been resumed at the Eskmeals experimental station and also at several of the universities. In the study of the use of stone dust in the limitation of mine explosions, the English investigators have made greater progress than has been achieved in the United States.

In France, it was observed that powdered coal has been widely adopted as a fuel. In Germany, near Hanover, novel methods are being employed in the distillation of brown coal, a lignite quite different from American lignites, from which various valuable oils, paraffin, and gas are being obtained. At Whitehaven, England, coal is being mined under the sea at a point 4 1-2 miles from the shore line.

Owing to the scarcity of timber, various substitutes are being employed in the different countries for mine props. Steel props and steel arches are being used extensively to hold up mine roofs. In Belgium, mine shafts in wet, "running" ground are being constructed largely by the freezing process, in which the ground is frozen and made easier of excavation through the medium of refrigerated brine forced through pipes surrounding the area to be excavated. Shafts more than 600 feet in depth have been sunk by this method. A great amount of information bearing directly on other mining problems forming a part of the investigative program of the Bureau of Mines was obtained by Mr. Rice.

International Co-operation in Research Proposed

Mr. Rice reports that the research agencies of the various European governments were greatly interested in the experiment of the Bureau of Mines and other scientific bureaus of the American Government and were quite anxious to co-operate in the study of different problems. As a representative of an American governmental research organization he was given an extremely cordial reception by the scientfic workers of all countries visited. As a result of his visit to England, the British Government has already proposed, through the State Department, that a joint program f research, covering various mining problems, be adopted. This program would include the exchange of technical information, of materials under test, of scientific apparatus, and possibly of research personnel. This proposal has been accepted by Secretary Work.

THE PROBLEM OF MINE VENTILATION

Many metal mines in the United States have unsatisfactory ventilation systems, with the result that employees frequently work under conditions which are unhealthful and which materially reduce efficiency, states the United States Bureau of Mines as the result of studies made by its engineers. High temperatures and humidities, which unduly deplete the miners' vitality, and prevent his working full time and which may undermine his health, are encountered in many mines. Workers at faces frequently breathe air impregnated with large quantities of fine mineral dusts. Physical examinations of such workers indicate that the continued breathing of such air injuriously affect the health of workers, especially if the air is stagnant, or hot and stagnant. While siliceous dust is probably the most dangerous, dusts low in silica are also known to be harmful. In some instances, the air in mines has been found to be unduly depleted of oxygen or to have a high content of gases such as carbon dioxide or even of the poisonous carbon monoxide.

Remedial measures suggested by the Bureau of Mines are the adoption of mechanical ventilating methods giving circulation of pure air at working faces, together with the use of devices and methods for reduction of air dustiness, including the use of wet drills and the sprinkling of mine workings, muck piles, etc. While much remains to be done in many mines and mining districts to attain a reasonable degree of safety and efficiency along the above lines, especially in the application of proper measures, not a few metal mines throughout the country have adopted all or some of the bureau's recommendations for better ventilation and dust elimination. In one mining district where health and efficiency were especially poor due to underground conditions, the many changes towards better ventilation and reductions of air dustiness caused a large insurance company to reduce premium rates as much as 50 per cent.

STRONTIUM

The commercial source of strontium is the minerals celestite (strontium sulphate) and strontianite (strontium carbonate), the former being the more common. A recent report lists the ground mineral at $80 per ton in the United States. About 2,000 tons is used there annually. This amount would be increased largely were a beet sugar industry established, as this provides the chief use for strontium salts. Coloured fireworks and signals and certain medicines constitute the other uses.

MOLYBDENITE

Molybdenite is found in the contact zone of pegmatite granite with crystalline limestone, where it is commonly associated with pyrite, pyrrhotite, pyroxene (diopside), and scapolite. It is also found in the pegmatite dikes themselves, and, sometimes, in aplite dikes. Ores containing as low as one per cent of molybdenite can be worked at a profit since the oil flotation process has been applied to the mineral.

THE MINING DISTRICTS

By THE JOURNAL'S CORRESPONDENTS

NORTHERN ONTARIO

South Lorrain.—During the month of September Keeley Mines in South Lorrain produced 135,400 ounces of silver. The enlargement of the mill is practically completed, and within the next couple of weeks the company should be in a position to treat 140 tons a day, which will materially increase the output. Development work is proceeding on the 8th level, and within a few weeks the drift should be under the famous ore-shoot on the 7th level of No. 26 vein. The new level is particularly important, as it will determine whether or not the zone of secondary enrichment has any further depth. No. 26 vein produced over 300,000 ounces from a short drift, the vein in one place having a width of approximately 5 feet of high-grade ore running about 7,000 ounces a ton. The company has about 200,000 ounces of high-grade ore stored underground.

Engineers of the T. & N.O.Ry. Commission have started trial survey lines from Cobalt to South Lorrain. Three different routes will be surveyed, the one from North Cobalt following the line of the motor road, another from the end of the Kerr Lake branch of the Nipissing Central and the third leaving the main line three miles South of Cobalt station. It is believed that the last route is the most feasible, but this cannot be accurately determined until the surveys are completed. The Government appears to be much impressed with the importance of the South Lorrain district, and it is altogether probable that the line will be constructed. Such a line would not only provide adequate transportion to the Gillies Limit and South Lorrain, but would also permit milling ores from South Lorrain to be brought to Cobalt mills for treatment.

It is expected that the Mining Corporation will shortly let a contract for sinking on the properties it has under option in the Gillies Limit. Some encouraging results have been encountered close to the surface, but to properly prospect the area it is necessary to sink approximately to the contact, which is about 400 feet deep.

Good progress is being made in the development of the Lorrain Consolidated. A crosscut is being run from the 260-foot level, which is expected to cut some of the veins within the next couple of weeks. One of these veins produced a small quantity of silver on the Belle Ellen property in the early days of the camp.

Cobalt. — The September report of the Nipissing states that during the month the company mined ore of an estimated net value of $172,000 and shipped bullion of an estimated net value of $130,000. The low-grade mill treated 6,858 tons, and the high-grade plant 131 tons. A total of 201,210 fine ounces of bullion was shipped from the refinery. A new vein was found on the 107-foot level of No. 26 shaft, which showed, in places, one inch of high-grade ore.

Kirkland.—Directors of the Lebel Lode Limited have been summoned to appear in the Cobalt Police Court to answer charges made by the Provincial authorities that the directors issued a prospectus which did not contain the information required by the law. The directors of the company claim that the prospectus itself contained all the necessary information, and would be sent to purchasers of shares, but that the company issued an advertisement offering to sell 100,000 shares, which did not contain all the statutory information required by the law. The directors claim that to do this would have required more money than they were able to spend. In a published advertisement one of the directors claims that the present Minister of Mines was a director in a company which advertised the sale of stock about a year ago, and apparently implies that in this company, as well, the law was not fully lived up to.

On the 600-foot level of the Lake Shore a length of approximately 2,000 feet in ore has been developed. The values on this level are reported to be higher than on the 400-foot level and are also more continuous. One stope, which has a length of about 350 feet, is stated to average $75 a ton and if this is so it is the richest stope in any of the gold mines of the Province.

The Highland-Kirkland is being unwatered and will again be worked. There is a shaft on the property 100 feet deep from which some drifting has been done, and these workings will be extended.

It is understood that satisfactory progress is being made in the re-financing of the Bidgood, and that if the present plans are carried out there will be sufficient money to complete the programme of exploration considered necessary.

The Tough-Oakes has started sinking the main shaft from 800 feet to 1,000 feet and two new levels will be opened. The more recent development on the property appear to have been most important, and it is stated that an ore-shoot 350 feet long, which carries values of $20, a ton over a width of 8 feet, has been opened up.

Porcupine.—Diamond drilling has been started on the Success property in Porcupine, which adjoins the Vipond. The property is operated by the Gold Acre Mines, a New York company.

Preparations are being made to continue the development of the Ankerite by English interests. The property was under option to the Coniagas some years ago, and the latter company did a large amount of work, but did not take up its option.

Five diamond-drill holes have been put down on the Martin property, which lies to the southwest of the Dome, and one hole is reported to have given an assay of $55 across 13 feet. Officials report that this drilling has indicated 100,000 tons of ore; but experience in Porcupine proves that diamond-drilling is not a safe guide for the estimating of tonnages. No underground work has yet been done on the property.

Thompson-Krist Company has issued a writ for damages against the Porcupine Crown Mines Limited. The action arises out of the operation of the old North Crown Mines, which was formed to take over and operate the properties of both companies. The Thompson-Krist was unable to provide its share of the funds, and bonds to the extent of $100,000 were foreclosed by

the Porcupine Crown. The latter company has recently removed the pumps and machinery from the mine, which is being allowed to fill with water.

The development of the Edwards lot is to be undertaken by English interests, who are arranging to purchase a mining plant to carry developments to a depth of 600 feet. The property consists of forty acres, on which there is a surface vein carrying low values. A shaft has been sunk to a depth of 50 feet. The property was diamond-drilled a few years ago by the Nipissing.

ALBERTA

Conciliation Board Presents Finding. — A decision of interest to the coal mine operators and coal miners of the Province of Alberta has been handed down by James Smith, Chairman of the Conciliation Board appointed to consider the evidence and render judgment on a dispute between the operators and miners of the Luscar Collieries, Alberta. Mr. Smith says:

"Under the agreement in effect between the United Mine Workers of America, District No. 18, and the Western Canada Coal Operators' Association, provision is made whereby in case of certain local disputes on which agreement cannot be reached, the Minister of Labour shall be called upon to appoint an independent or neutral chairman for the purpose of hearing case and rendering a decision thereon. For that purpose I have been appointed chairman by the Minister of Labour in the dispute at Luscar Collieries.

"On the 28th of September, 1923, the parties representing the United Mine Workers of America, District No. 18, and the Western Canada Coal Operators' Association, met in Edmonton and presented their case before me. The matter in dispute was in reference to payments made for coal taken from pitch pillars and entry or flat pillars, the coal in the former being conveyed to the car by means of chutes, while in the latter the coal will not run into the car under normal conditions and must be shovelled. The operators offered to pay 70c a ton for coal taken from pitch pillars and entry pillars, the same price for each, the representative of the miners asking 85c a ton for pitch pillar work and $1.05 a ton for entry or flat pillar work.

"I heard the evidence submitted and examined the documents, including the general agreement between the Western Canada Coal Operators' Association and the United Mine Workers of America, District No. 18, and I heard the arguments of both parties. The clause in the agreement admitted by both parties as applicable to the present dispute is as follows: 'In making the prices for new work the company shall be guided by existing prices in the same mine or other mines in the neighbourhood.'

"It was agreed by the parties that the price of pitch pillars at the Cadomin mine, a mine in the same neighbourhood and where conditions were similar to those at the Luscar Collieries, was applicable. That price at the Cadomin Mine is 70c per ton of 2,240 lbs., and I find that this price should govern pitch pillar work at Luscar Collieries.

"For entry or flat pillar work the representative of the miners finally asked for an addition of 20c for shovelling the coal over the amount of 70c for pitch pillar work, which would make flat pillar work 90c per ton, the operators adhering to their original offer of 70c per ton, the same as for pitch pillar work, alleging certain compensatory advantages in the mining which they claimed offset shovelling.

"To substantiate the men's claim I have been referred by Mr. R. Livett, representing the miners, to allowances made for shovelling coal in the Hillcrest mine, and in the Bellevue mine, and while these mines are not in the same neighbourhood as the Luscar, I have examined their rates and have given Mr. Livett's argument consideration.

"In the Hillcrest mine an allowance of 25c. per ton is made for loading into small cars. The mining rate, except for pillar work, is 76c per ton, and for pillar work is 61c per ton, being a difference of 15c per ton, which must be considered the advantage derived from pillar work mining. The mining and loading combined in pillar work is 86c. per ton, while the mining, without shovelling outside of pillar work, is 76c. per ton, making a difference of 10c per ton for shovelling, with the advantage claimed from pillar work mining.

"In the Bellevue mine the rate for loading, pushing, etc., coal which is mined from the crosscuts from up the pitch is 36c. per cubic yard. From this allowances for pushing and compensatory advantages of pillar mining should be deducted.

"Mr. Livett also put in evidence that at the Mountain Park, a mine in the same neighbourhood as the Luscar, by an agreement with the general manager, 20c a ton is allowed for shovelling. On reference to Mountain Park agreement, mining from pillars is given as 77c. per ton, while outside of pillars it is 85c. per ton, making 8c. a ton an advantage for pillar mining, which would leave 12c. a ton for shovelling.

"I have examined the rates of the Mountain Park and the other mines mentioned by Mr. Livett, and in all of them pillar work mining has certain compensatory advantages offsetting to a considerable degree the rate for shovelling outside of pillar work, this advantage running from 8c to 15c. a ton.

"The operators in support of their claim put in evidence that in the Diamond coal mine at Brule, a mine in the same neighbourhood, 8c. more per ton was allowed for mining for entry or flat pillar work than for pitch pillar work. It was admitted that no pillar work was done at Mountain Park Collieries, but that the rate of 20c. for shovelling coal was mutually agreed on and accepted by the parties as an order in full force, but it was claimed by the operators that advantages in pillar work existed in Luscar which did not exist in Mountain Park, and this offset to a great degree the price paid in Mountain Park paid for shovelling coal.

"It was admitted in evidence that approximately 50 per cent. of the coal in the entry pillars of Luscar Collieries would require very little actual mining and from this it was argued that the miner was to a great extent compensated for the shovelling required.

"Taking into consideration the evidence, the documents that were put in, the arguments presented to me, and the regard for the compensatory advantages from pillar mining, I am of the opinion that an equitable and fair allowance for entry or flat pillar work would be an increase of 10c. a ton, making in all 80c. per ton of 2,240 lbs. for entry or flat pillar work, and this is my finding.

"It was intimated by the operators that in certain parts of the flat pillar work chutes would be put in similar to those in pitch pillar work, thus eliminating

shovelling. If this is done so that shovelling is unnecessary, the increase of 10c. a ton for shovelling would not apply to entry or flat pillar work.

"I was greatly impressed with the earnestness, reasonableness and conciseness with which both parties presented their view, and the pains they took to make the dispute clear was of valuable assistance to me in making my finding."

BRITISH COLUMBIA

Dr. Schofield in Hong Kong. — Dean R. W. Brock, geologist, of the University of British Columbia, after attending the Pan-Pacific Scientific Conference at Sydney, New South Wales, and making a tour of parts of the Orient, has returned to Vancouver. The British Government has placed Dean Brock in charge of geological survey work at Hong Kong, China, and he has made a rough reconnaissance. Dr. S. J. Schofield, also of the University of B. C., has left to continue the work in Hong Kong.

While in Australia Dean Brock was one of a party, made up largely of scientists from the United States, who visited the various States composing the Commonwealth. He says that all nations interested in the Pacific, with the exception of some South American lands, were represented at the Conference and that the next gathering of the kind will take place three years hence in Japan.

In giving his geological impressions of the islands of the Pacific, Dean Brock, said, with reference to the Fiji Islands, that without doubt they belonged to the continental group.

Lardeau Operator Dies. — Wm. F. Cochrane, known as the "King of the Lardeau," a mining division lying in the Kootenays to the south of Revelstoke, died recently in Vancouver. He was the younger son of the Senator Cochrane, of Hillhurst, Quebec, and going to the Lardeau in 1900 lived there, an active mining operator, until 1914. He was associated with W. B. Poole, now of the Reno Mine, and C. S. Young, of Calgary, in forming the Great Northern Mines Ltd., which operated a number of mines in the Lardeau, including the Lucky Jack at Popular.

Rossland. — Free gold is reported to have been struck on the "O.K.", adjoining the I. X. L., and it is said that the ore-body is sufficiently well defined to give promise of persistence. With regard to the high values now being secured from the ores of these Rossland properties, it is interesting to note that the Department of Mines has had to pay $20 for a small though striking sample of the mineral for display at the forthcoming British Empire Exhibition.

New Placer Field Reported. — Reports are reaching the Pacific Coast of a new placer gold strike in the Kalem Lake region which is in northern British Columbia off the Grand Trunk Pacific Railway. Promising claims are said to have been staked at the head of Kalem Lake in the Rosswood District, about 28 miles from Terrace on the G. T. P. Prospectors have been quietly leaving Smithers and neighboring towns en route to the district.

Market for B. C. Coke. — The British Columbia Products Bureau of the Vancouver Board of Trade has become interested in the statement of a correspondent, William J. Auw, of South Pasadena, California, that there is a market in that State for coke of a good blast-furnace quality. Mr. Auw expressed the view that there should be a good market for such coke delivered at Los Angeles harbor. As United States coke enters British Columbia free of duty, the same material exported from Canada would receive the same treatment in crossing the line. Mr. Auw's representations will be laid before provincial producers of coke.

Alaskan Gold Mining. — From Fairbanks, Alaska, comes the statement that the gold output of that territory this year will be exceptionally high. It is likely to be double that of last year according to some operators. On Caribou Creek there has been much activity and the first clean-up on the Airship Mine was larger than was expected. The construction of the new depot at Fairbanks, the initiation of work on terminals, and general industrial progress, has brought prosperity and confidence to the territory. It is reported that important copper deposits have been located in the Kashwitna section, 40 miles from the Alaska railroad in the interior, and a pack trail to the district has been opened.

Salmo. — Harold Lakes, of the Nugget Gold Mines, Salmo, reports that his Company is exploring thoroughly the possibilities of the Golden Bell Mine, adjacent to the Nugget.

Kaslo. — British interests represented by Mayor James Anderson, of Kaslo, are expected to re-open the Jackson Mines, which include the Northern Belle, Kootenay Star, Labor Day, Ophir, Congress and Dublin Queen, all early locations. The property is equipped with a concentrator and tramway and has shipped approximately 4,000 tons of high-grade silver-lead concentrate. It has been idle for some fifteen years. R. H. Stewart, formerly general manager of the Consolidated Mining and Smelting Co., is mentioned as likely to be the consulting engineer of the company. Important showings, it is said, have been found on the Dublin Queen as a result of development work Mr. Stewart has been directing.

The moving of the Kaslo mill to the Stemwinder Mine near Kimberley is contemplated by M. S. Davys who proposes adapting the plant, with some additions, to the treatment of the ore of the latter property.

The Gibson Mine is to be further developed by the Daybreak Mining Co., which succeeds the Gibson Mining Co. J. C. Roberts, president of the former Co., and Robert Gunning, of Portland, Ore., a large shareholder, recently visited the property. A contract is being let for the driving of 1,000 feet of tunnel and bunk houses are being built for the housing of the workmen.

Sandon. — The finding of a large body of ore on the Ruth, Sandon, has led to the belief that the continuation of the lead of the Silversmith Mine has been located.

Stewart. — The American Mining & Milling Co., is reported to have had a favorable report from their consulting engineer, Andrew Larsen, with respect to the results of development work on their properties on Fish Creek and in other parts of the Portland Canal district. Grant Mahood has resigned as president of the Company and is being succeeded by Major W. G. Swan. The International Financiers Ltd., a new Company, has been formed by Mr. Mahood and is said to have unwritten the entire treasury stock of the parent Company. The American Mining and Milling Co. has options on some Georgia River properties, Portland Canal, and is acquiring control of others in that locality.

Alice Arm. — The affairs of the Dolly Varden Mine appear to have been put in satisfactory shape following the foreclosure proceedings initiated by the mortgagee, George Wingfield, and his associates. The holdings first were turned over to the Northern Mining Properties Ltd., in which Mr. Wingfield was a large stockholder. Then the Dolly Varden Properties Ltd., was organized, to which the mine and plant have been transferred, and this Company holds the railway under a 999 year lease. It was reported recently that the Dolly Varden had been sold but there is no official confirmation of this, although it is expected that definite action will be taken before long in regard to the further development of the claims known as the Dolly Varden group.

Trail Ore Receipts. — Ore receipts at the Trail smelter, Consolidated Mining & Smelting Co., for the last nine days of September totalled 4,947 tons, made up as follows:

	Tons
Alamo, Alamo	55
Eholt Mining Co., Eholt	3
Granite, Taghum	8
Knob Hill, Republic Wn.	174
Lone Pine-Surprise-Last Chance, Republic, Wn.	314
Quilp, Republic Wn.	194
Silversmith, Sandon	140
Sally, Beaverdell	34
Van Roi, Sandon	28
Company Mines	4,029
Total	4,979

During the first months of the year the weekly receipts averaged 9,000 tons. In the past six weeks they have dropped to about 4,500 tons, which is explained by the fact that the product of the Big Sullivan Mine now is reaching Trail as concentrates as a result of the opening of the Kimberley mill.

September Coal Production. — British Columbia's coal production for the month of September totalled 181,634 tons, a drop as compared with the previous month of 40,662 tons.

Of the total output for the month the Vancouver Island mines were responsible for 121,880 tons, approximately 67.1 per cent of the total, which is 14,067 tons under the production of August.

The Nicola-Princeton mines produced 18,978 tons, a decrease of 2,613 tons in comparison with the output for August, and about 10.4 per cent. of the total production.

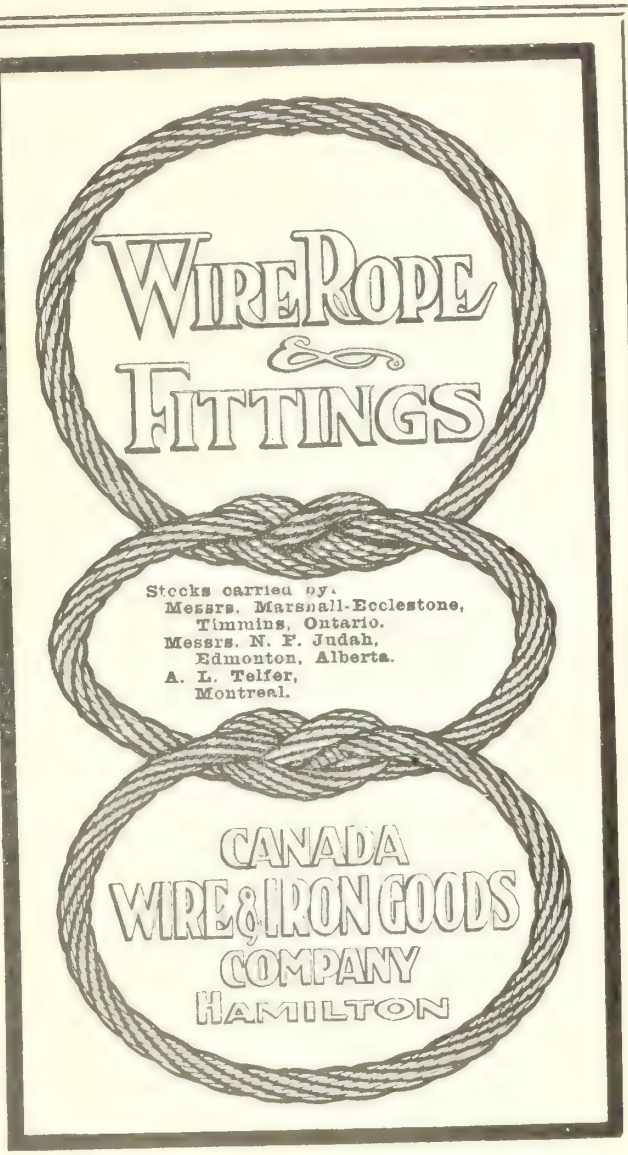
The Mines of the Crow's Nest Pass district produced 40,776 tons, which is 23,982 tons under the August figure and some 22.5 per cent. of the total for the province.

All the Vancouver Island mines show a decline with the exception of the Canadian Collieries (D) Ltd., Comox Mine, which has an increase in comparison with August of 689 tons, and Messrs. King and Foster, Old Wellington Mine, which shows an increase of 7 tons.

The Nicola-Princeton collieries all have dropped in output.

In the Crow's Nest Pass the Corbin Colliery alone shows an increase. Its output is 739 tons better than it was in August. The other collieries, however, have dropped materially.

It is expected the iron ore shipments from the Lake Superior region will reach 60,000,000 tons during the present season. Last year the total was 12,000,000 tons.



The contributing factors in making good Wire Rope are:

Men who know how
The best grade of materials
The most Modern Machinery

We have all 3 and are producing the goods. Give us a trial.

Our Wire Rope Catalogue is an invaluable reference book and contains many helpful ideas on the care of wire ropes and cables as well as information on the best kind of rope to use on all classes of work. A copy sent upon request.

Our other lines of Manufacture are Wire Cloth for all uses, Perforated Metals, Wire Pulp Mats, Clothes Lockers, Machinery and Window Guards, Pulp Mats, inquiries solicited.

SALES ENGINEER FOR MINING EQUIPMENT

will shortly be free to consider new connection.

Fifteen years experience in selling and as manager of well-known companies.

Complete information by mail or personal interview.

APPLY — Box 607, Canadian Mining Journal, Gardenvale, Quebec.

INDEX TO MINE AND MILL SUPPLIES

Addresses of advertisers whose names appear in the following classified index, may be found upon reference to their advertisements. An alphabetical index to advertisers will be found on the page facing the inside back cover. The following regulations apply to all advertisers: — One-eighth page, every issue, three headings; one-quarter page, every issue, six headings; one-half page, every issue, twelve headings; full page, every issue, twenty-four headings. Buyers who are unable to find in the classification here given such machinery or supplies as they desire are invited to write Service Dept., Canadian Mining Journal, Gardenvale, Que., who can, in all probability, refer them to proper sources.

Acetylene Lamps:

The Hardinge Company Inc.
120 Broadway,
New York N. Y.

Gentlemen,

Attention Mr. V. A. Stout.

In reply to your letter of the 6th March I have pleasure in advising you that the 6-ft x 22-in Hardinge Mill which you supplied to us last year is giving satisfaction and that we are presently negotiating with your Salt Lake City office with regard to the purchase of a larger Mill.

Yours faithfully.

General Manager

Sink your Shafts with "Jackhamers"

REG'D THE WORLD OVER.

SHAFT sinking perhaps more than any other phase of mining has benefited by the "Jackhamer." These one-man, hand hammer drills are ideal for down-hole drilling and for work in close quarters.

Today many mines are using the heavier types of "Jackhamer" drills — "DCR-23" and "DDR-13" —because of their power, speed, and ability to drill deeper holes. These types use 1 or 1⅛-inch steel. They were built for shaft sinking.

"Jackhamer" drills are made of forged steel, have hole-blowing device, strong steel retainer, rubber grip handles and automatic lubrication system — features which have marked the superiority of the "Jackhamer" since its introduction.

"Jackhamer" drills are now made in five weights. The three largest ones may be used with either steam or compressed air. They may also be equipped with or without arrangements for feeding water as well as air through the drill steel to the bottom of the drill hole to lay the dust and remove the cuttings.

Ingerso

Compressors **Rock Drills** **Sharpeners**

Although "Jackhamer" drills are principally used for down-hole drilling, and for service where the machine may be held in the operator's hand, mountings are made for the three larger sizes so that they may be used for incline raises or other work where heavier drills are clumsy and difficult to set up. They may also frequently be used to advantage for regular drifting and tunnelling work.

It requires only a few moments to mount or demount your "Jackhamers" and their range of work is thus greatly increased.

Bulletin 4046-c describes the entire "Jackhamer" family

Bulletins sent on request.

Ontario's Minerals

PROVINCE OF ONTARIO

Hon. CHARLES. McCREA, Minister. DEPARTMENT OF MINES *Thos. W. Gibson*

Mineral Areas

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favourable for the occurrence of minerals 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver veins of Cobalt, Gowganda and South Lorrain occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

Economic Minerals

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario: — actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluorspar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, Portland cement, brick and tile, meet every demand.

Mineral Production

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1922 to be worth $62,202,169, of which the metallic production was $38,190,711.

The following figures show the growth of Ontario's mineral industry by five-year periods since 1891 when a Bureau of Mines was first established.

Year.	Value.	Year.	Value
1891	$4,705,672	1911	$41,976,797
1896	5,235,003	1916	65,303,822
1901	11,831,086	1918 (Maximum war output)	80,308,972
1906	22,388,383	1921	48,128,387
	Dividends.		

Dividends and bonuses paid to the end of 1922 amounted to $28,096,699 for gold mining companies, and $86,238,185 for silver mining companies or a total of $114,334,884.

Mining Regulations

A miner's license costs $5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of $2.50 or $3.00 per acre, depending on location in unsurveyed or surveyed territory.

Assay Office

The Provincial Assays Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

Accompanying The Mining Engineer

The Imperial Bank is particularly adapted to the needs of the mining engineer. Wherever he may go in the Dominion this Bank accompanies him.

Every branch of this Bank — and there are 192 throughout the Dominion — is fully equipped to render an adequate banking service. The managers of our branches in the mining areas, because of their intimate knowledge of local conditions, can impart valuable information to those engaged in the mining industry.

You will never be far from your bank account if you deposit your funds with the Imperial Bank.

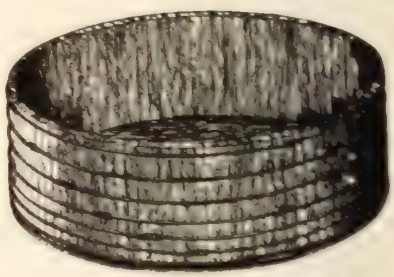
TORONTO MINING TANKS



The life of Wooden Tanks depends chiefly on the Quality of the Lumber used in their manufacture.

The Fir used in the manufacture of TORONTO Tanks comes from British Columbia — only the finest quality procurable is sawn for our No. 1 Clear Tank grade stock - a tight grained wood — free from sap, shake, hearts and all knots, excepting a few fine pin knots.

Cypress and White Pine are similar in quality to our B. C Fir although more adaptable in special installations.

TORONTO No. 1 Tank Grade lumber is the finest quality sawn - thoroughly air dried before being made into tanks. The user is assured of a most satisfactory product.

TORONTO Tanks are made for any purpose - of any size for all needs. Send for catalogue.

:-: EDITORIAL :-:

OVERSEAS PARTNERSHIPS REQUIRED

The Prime Minister of Canada has repeated his request to the British public for men and money to assist in settling our land, developing our natural resources and expanding our manufacturing activities. This was the substance of his first address on landing in England, and now, towards the end of his visit, he repeats it. The topic is certainly of sufficient importance to warrant repetition again and again; but we are rather fearful that the impression will spread abroad in Great Britain that Canada's attitude to the mother country is that of a child to its parent, rather than that of the full-grown daughter, who is in charge of her own house and wishes merely the coöperation and mutual support that is the essence of natural family relations, where grown-ups are concerned.

Let us take the case of mineral resources. It has been demonstrated conclusively that long-distance investment in Canadian mines, without adequate personal contact, is almost bound to end in disaster. Commencing with Rossland over quarter of a century ago, there has been a series of failures resulting from the direct control from London of mining enterprises in this country. The few exceptions serve but to accentuate the difficulties that attend long-distance management. Today we see exemplified a much sounder and more successful type of overseas investment. British and Canadian capital is joined in mining ventures, and its expenditure is being directed by men, most of them natives of this country, thoroughly familiar with our conditions and competent to make the most of the money entrusted to their care. There are numerous examples of these Anglo-Canadian companies, and, fortunately, their number is increasing rapidly.

We should like, therefore, to couple with Mr. MacKenzie King's request for British capital a statement, on behalf of our mineral industry, that it is a partnership arrangement that we wish to have. It is from the mutual responsibilities of a partnership that both we and they will get the best result. We have now an adequate corps of technically proficient mining men to direct the whole of our industry. We have likewise various groups of well-tried mining investors thoroughly equipped to expend their funds judiciously and profitably. These engineers and investors are better fitted to handle mining development and operation in this country than are outsiders without their intimate knowledge of Canadian conditions. We can make good use of British capital in finding and developing new mines; but it will be most wisely expended under the direction of an Anglo-Canadian partnership.

AN IMPERIAL DELEGATE

On Monday of this week mining men in Vancouver welcomed to Canada a representative of the mining men of Great Britain in the person of Mr. Hugh F. Marriott, Past-President of the Institution of Mining and Metallurgy. Mr. Marriott has been delegated by this institution and the Institute of Mining and Metallurgical Engineers to make a tour of the Empire on behalf of the forthcoming Empire Mining and Metallurgical Congress, to be held at the British Empire Exhibition in June, 1924. He comes directly from Australia and New Zealand, where he has interviewed the members of the mining and metallurgical societies on behalf of the Congress.

Mr. Marriott's object in visiting Canada is twofold. He wishes to inform us about the forthcoming Congress, its aims and its proposed activities, and he also wishes to gather at first hand information as to the views and inclinations of Canadian mining men. To this end an itinerary has been arranged for him by the Canadian Institute of Mining and Metallurgy that will give him an opportunity of conferring with the members of each of the Institute's branches, from British Columbia to Nova Scotia.

The objects of the proposed Empire Congress have been set forth in these pages before, but they will bear repetition on this occasion. The proposals involve a federation of the mining and metallurgical institutes of Great Britain, the Dominions and other parts of the Empire, the chief objects of which will be:

(a) To serve as an organ of intercommunication between the co-operating institutions and to promote the interests of the professions and industries.

(b) To create and maintain throughout the Empire a high standard of technical efficiency and professional conduct.

(c) To convene at regular intervals an Empire Mining and Metallurgical Congress.

Already the leading mining and metallurgical societies of Great Britain have subscribed to the idea, and it is hoped that, as a result of Mr. Marriott's visit, the names of the institutes in Canada and the other Dominions will be added to the list.

PROGRESS OF HURONIAN BELT COMPANY

Today we print an account of the annual meeting of the Huronian Belt Company, which is becoming rapidly an important factor in the exploration and development of mineral lands in eastern Canada. Particularly noticeable is the vigour and acumen with which the primary work of prospecting and the initial development of prospects has been conducted by the management. The operation best known to the public is the resuscitation of the two expiring mines, Keeley and Vipond, and their return to healthy and useful lives, which we expect will be long as well. The management of these is being conducted in a straightforward way, which augurs well for the status of new mines that may be added to this first pair. The Vipond operations are still, unfortunately, being carried on under the shadow of stock exchange operations that can bring it no credit; the Keeley suffers from no such incubus.

The success of the Huronian Belt Company up to the present is due primarily to a scientifically conducted course of investigation, based on geological grounds. The wonderful ore-shoots at the Keeley would still remain hidden had not Dr. Bell studied the ground, divined Nature's secret, and put his conclusion to the test. Similarly acute and sound was the reasoning that has directed the expenditure on the moribund Vipond property. In both these cases the investment required has not been of serious dimensions, as mining investment goes; the prime factor has been the human capacity for geological deduction and the decision to spend the money on geological advice. Not every venture will turn out so successfully as have Keeley and Vipond; but these two "hits" will cover amply the cost of many "misses."

It is in the newer camps that the Company's progress in the immediate future would seem to be centred. The annual report gives a list of holdings in a number of promising localities. A good deal of vigorous work has been done already on these claims and on some of them intensive prospecting has disclosed showings of ore that warrant a considerable additional expenditure. We may, therefore, expect that the next annual report of the company will record, not only further progress in the two established mines, but an addition to their number.

PEAT SUPPLY ASSURED FOR 1924

Some time ago we referred in these columns to the order-in-council at Ottawa that authorized the Department of Mines to turn over the peat plant at Alfred, Ontario, to private interests, provided the applicant gave evidence of his good faith and of his ability to finance the operation of the plant. The Ontario government concurred in this arrangement, and it remained only to find a man ready to undertake the venture. Such a man has not been easy to locate peat has a bad name in Canada, due to former unsuccessful attempts to use it.

Now the man has been found. His credentials have been examined by representatives of the government at Ottawa and Toronto and have been found to be thoroughly satisfactory. He is already involved in fuel supply on a large scale, and has bought and distributed a considerable fraction of the peat made at Alfred during the experimental operations. He is familiar in detail with the plant and its operation, as well as with the cost of its product. He is satisfied that the Anrep-Moore peat plant is capable of making good fuel at a profit, and has backed this belief with his money. The government now holds his bond for a large sum, and he owns the plant at Alfred, subject to the conditions of the bond, chief of which is the stipulation that the plant shall be operated next summer.

The present owner of the peat plant is not able alone, to finance the operation of the peat plant next summer. He intends, therefore, to ask for the cooperation of others interested in the commercial establishment of a peat industry. A company with a modest capitalization is in process of incorporation and the stock will be offered for public subscription. The technical authorities of both governments, possessed of full information, have already recommended the project to the public for investment. There is no doubt that the public will respond.

TRAIL MEETING OF THE INSTITUTE

Trail is the seat of Canada's largest group of metallurgical plants. Its products are diversified and some of the processes used are unique. At the meeting of the British Columbia Division of the Institute at Trail two weeks ago the visitors were shown through the plants, and their operation was explained. Much of the information divulged on this occasion is now made public for the first time. It will add largely to the creditable record of Canadian metallurgists. The same can be said of the smelting process at Anyox and of the new concentrating plants at Kimberley and Britannia, which were also discussed at the meeting.

The proceedings of this branch meeting of the Institute, reduced to the printed page, will serve well to illustrate the performance of one of its chief functions. The annual volume of Transactions is the repository of mining and metallurgical information, both technical and historical, and it is worth the best efforts of those engaged in the active pursuit of the sister sciences to add their quota to the record as occasion offers. For generations to come these volumes will be consulted by our successors. We are confident the record will be well worthy of this present generation of miners and metallurgists.

Institute Meeting at Trail

Papers on Sullivan and Rossland Mines, the Smelters, Refineries and Concentrators, and Prospecting. Visit to Rossland Mines.

The annual meeting of the British Columbia Division of the Canadian Institute of Mining and Metallurgy, was held at Trail, B. C. October 17th to 20th, and has proved to be an event of great importance in the annals of the Institute. The local committee, with the whole-hearted support of the staff of the Consolidated Mining & Smelting Co., made excellent arrangements for the meeting, and both the local members and the delegates from the Coast and other points agreed that the results were of the most important and encouraging nature.

The program of papers that had been arranged included description of operations at three of the most important mining centres of British Columbia, and these subjects were dealt with in a way that marked these contributions as of more than usual importance. The problems that have been faced and overcome, and the operations that are being carried out by the Consolidated Mining & Smelting Co., the Granby M. S. & P. Co., and the Britannia Mines were published for the first time, and aroused a high degree of interest. In addition to these papers Mr. Guernsey gave an account of the Sulphur industry and Mr. S. S. Fowler gave a fascinating account of the history of mining in the Kootenays.

Scientific Direction for Prospecting

In presenting Dr. W. L. Uglow's paper on "Undiscovered Mines in B. C.," Mr. H. G. Nichols said that the purpose of the paper was to note the passing of the days of mines with outcrops, and the consequent influence upon prospecting and investment. The reasons for believing that deposits exposed at the accidental surface form but a part of the orebodies of B. C. were discussed, and the handicaps to the prospector in his search for buried ore were outlined. The elimination of the attraction of quick returns also affects the attitude of capital towards prospecting. Long chances are becoming things of the past and the investor wants to be shown more and more why he should speculate in mining.

Methods for the assistance of prospecting in assuming the added burden entailed by these conditions were referred to, and among them particular reference was made to the researches in electrical prospecting. Most important of all is the aid that is to be found in the direction of prospecting by the application of geological reasoning. We engineers and geologists are not the only ones who are aware of the growing disability of the old-time methods to cope with present conditions. The investor is also fully aware of it, and attempts to conceal it, by ultra-optimistic representations of possibilities, only serve to reduce confidence. Our aim today should be to inspire confidence, and this may be done best by adopting methods that will commend themselves by serving to reduce the risks of prospecting.

A keen discussion was also initiated by Mr. C. M. Campbell's paper "Publicity in the Mining Interest."

The subject of the Iron and Steel industry was also discussed at a business meeting in Rossland on the 17th inst. The particular subjects of interest that were dealt with at this meeting will be referred to in detail next week.

Growth of Sullivan Mine

S. G. Blaylock, General Manager of the Company, told of the staking of the "Sullivan" over thirty years ago by Pat Sullivan and party, four claims being located which later became the "Sullivan Mine." Development was accelerated by the railway, which was constructed in 1898 and 1899. In 1900 a compressor was installed and the first shipments of silver-lead ore made. Over 300,000 tons of ore were developed and then a smelter was thought necessary. The work was started but was never completed. The mine had closed in 1907 and in that year it was leased by the Consolidated. The ore was tested, a sorting plant installed, and thereafter the Consolidated obtained full control. Development continued and production grew as follows: 1910, 23,000 tons; 1911, 24,700 tons; 1912, 28,650 tons; 1913, 31,000 tons; 1914, 36,000 tons; and 1915, 44,500 tons.

The workings of the "Sullivan Mine" were well described by W. M. Archibald, Manager of Mines, who referred to the recent installation of electric hoists and windlasses, of new compressors and larger gauge tracks, of modern accommodation provided for employees, and of the establishment of a hospital and a resident physician at Kimberley.

Concentrating and Smelting

Electrolytic smelting and the treatment of zinc ores were dealt with by B. A. Stimmel, while concentrating methods were spoken of by R. W. Diamond, superintendent of the Concentrating Department, and E. M. Styles, designer of the Kimberley Concentrator. The process of refining at Trail was the subject of an address by George Murray, assistant superintendent of the Consolidated.

Nichol Thompson, of Vancouver, who recently returned from England, predicted that there would be a flood of British capital for development of provincial minerals if the "prospectors would come down to earth." He had reference to valuations placed on prospects.

Texas Sulphur

The sulphur deposits of Texas were described with the assistance of illustrations by F. W. Guernsey and it was noted, as a matter of interest, that the directors of the industry were former residents of Trail. W. H. Aldridge, head of the enterprise, was general manager of the Trail Smelter for a number of years; R. H. Stewart, of Vancouver, another former general manager at Trail, was consulting engineer of the Texas industry; Charles Beisel, at one time resident in Trail, is the general manager. The Texas Plant supplies sulphur for the pulp manufactures of the Province.

Ninety Miles of Underground Workings

The Leroi Mine, Rossland, was visited under the guidance of Mr. Archibald and E. D. Peters, superintendent. Delegates were shown the 800 and 1,650-foot levels and were run for a mile underground by electric tram to West Leroi ground, where a gold-copper vein has been developed, 400 feet long and twenty feet wide. It was explained that the Rossland Mines have about ninety miles of underground workings and that, with the acquisition of the Leroi No. 2, the Consolidated now is operating all the developed mines of the camp. The mines have a maximum depth of 2,600 feet, being sunk to the level of the Columbia river at Trail, and with the completion of the Kimberley Smelter and the consequent relief of pressure at Trail work at Rossland is being stimulated, the force now totalling 225 men with more being added as the company's plans are put into effect.

Portland Canal Gold-Silver-Lead Mines

By ALEXANDER GRAY

The uniform courtesy that has characterized the conduct of Dr. H. A. Guess, Vice-President and Managing Director of the Premier Gold Mining Company and his readiness to co-operate with all who are constructively interested in those mineral developments in which he has played such a conspicuous part, make it possible to present up-to-date facts about British Columbia's chief precious metal producer. A glance at the topography, the heavy timber, and the towering peaks round about the Premier, Indian, B. C. Silver, Big Missouri, and other properties as indicated in the accompanying photograph, make it quite comprehensible why Portland Canal areas had to await the coming of influential capitalists. A region so remote and rugged, that Dr. Guess and his principals had to construct an aerial tramway to tidewater, a distance of eleven miles, has all the glamour of mining in the western ranges. Bunting and Bush and their contemporaries, therefore, and even the Clothiers, who staked the Indian properties; "Koolgardie" Smith, Leckie—all who acquired Portland Canal areas a decade and a half ago—after having made discoveries, were compelled to realize that mines so situated are slow assets when removed from the quickening influence of large capital and adequate technical skill.

Without the Premier Mine and its Guggenheim-Keith-Neill-Trites-Wood-Wilson-Untermeyer control, the Indian Mines might have remained a debatable prospect, the Big Missouri a perennial disappointment, the B. C. Silver Mines unexplored, and the neighboring areas now acquired by strong combinations would have continued to be a part of past history. Primarily Neill and his colleagues, who found the Premier, made Portland Canal a field for mining enterprises of magnitude. English, American and Canadian capitalists are now competing in friendly rivalry for what was condemned over and over again. Instead of being "property poor," those who held on to the ground, or who acquired it at distress prices, are being compensated for the years of hope deferred since 1911, when Bush could not interest anyone long enough in the Premier B. C. Silver and the Bush; the Lindeborgs could not let go of the Big Missouri, and Leckie was locked up with the Hercules. The Clothiers had more faith in the Indian than others would show with their money.

New Era with Big Milling Capacity

A 1,000-ton mill to treat the Premier lower-grade ores; probably a railway to serve the district; a mill of undetermined capacity for the Indian; reports that individual Premier directors who took over the Premier property from Bush have been fortunate with their Big Missouri venture; the acquisition of the Hercules by Toronto people; the tentative deal with the Forty-Nine on behalf of London principals; all certify to the substantial character of the Portland Canal movement, which so impressed Mr. Leopold Albu, Managing Director of the Albu General Mining & Finance Group of the Rand, that upon his return to London he stated publicly his optimistic view regarding the future of this British Columbia district. Therefore, what the Sullivan Mine and Trail metallurgy did for the Fort Steele mining division, what Granby operations provided at Anyox for the Naas district, what Howe Sound did for its secttion,—this the Premier company has accomplished for the Portland Canal Mining division.

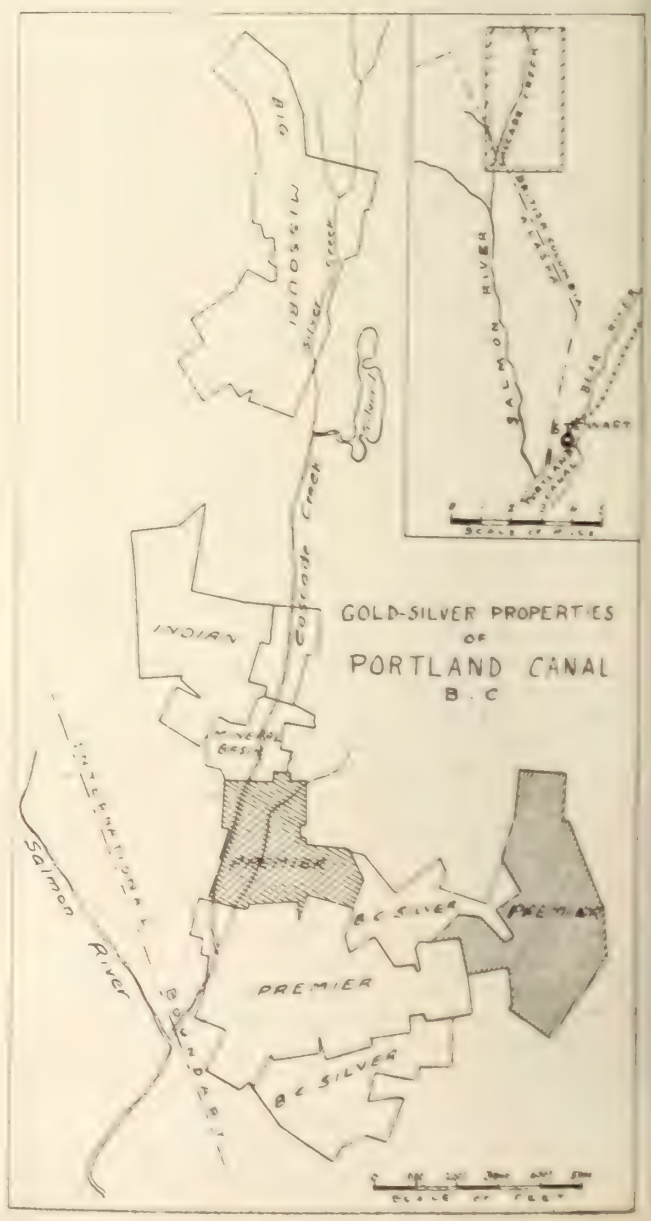
Official documents attest the predominance of the Portland Canal output in precious metals, the 1922 report of the Minister of Mines containing the following:

"The value of lode gold produced in 1922 was $4,089,684, as compared with $2,804,154 in 1921, an increase of $1,285,530, or about 45.9 per cent. The Portland Canal Division, of this, produced a gold value of $2,553,303, or more than the remainder of the Province.

"The feature of the year has been the phenomenal silver production of the Portland Canal Mining Division, which amounted to 4,264,228 ozs. valued at $2,735,076, almost entirely by the Premier Mine.

"The Indian Mines is looking very promising for the amount of work done and is developing large bodies of milling-grade ore. Indications are that this property will justify its being equipped with a concentrating plant within a year.

"The B. C. Silver Mines' recent strike in cutting the extension of one of the important ore-producing fissures of the Premier mine, and the satisfactory values obtained across a width of 25 feet, practically indicates its developing into a very important producer."



Influence of the Premier Emphasized

Pursuant to this review, it is pertinent to further quote ne official report of the Mining Engineer for the Portland anal division as follows:

The fact that the Premier mine of the Premier Gold Mining Company has produced in the last four years approximately 170,000 ozs. gold and 5,650,000 ozs. silver, r about $8,000,000 of which the greater portion is this ear's output, has brought this area prominently before the whole mining world. As a result, this year has had the reatest amount of development done in this section. The esults have more than fulfilled expectations. The ore-odies of the Premier mine have been proved by diamond-rilling to greater depth, showing the values and extent f the ore-bodies to be very gratifying.

"The Indian Mines, Limited, has had about 1,000 feet f development work done on it, on three levels, in drift-ng, raising and crosscutting, exposing a big tonnage of ood-grade milling ore, as well as an appreciable tonnage f shipping grade. The British Columbia Silver Mines, imited, has also done about 1,000 feet of underground work, mainly in driving a crosscut tunnel, toward cutting he extension of north-east of the Premier quartz porphy-ies. This objective was reached early in 1923, the tunnel rosscutting through about 25 feet of mineralized ground, no doubt the extension of one of the Premier fissures, and stated by the manager to carry satisfactory values. Though the ore-body has not been explored to any extent at the time of writing this, there is every reason for believing that the strike is important, and that the property can now be developed into a big enterprise.

"The summer's development on the Big Missouri ground gave sufficient encouragement for the payment of the second installment on the purchase price, and work will, I understand, proceed as soon as conditions permit.

"The interesting of Toronto and Montreal capital in the development of the Indian and Mobile, of English capital in the operations of British Columbia Silver Mines, Limited, and British Columbia capital in the exploration of the Big Missouri, are significant facts and may bring far-reaching results. There is no doubt that next year's operations will greatly exceed this year's and will go a long way towards putting these mines in the shipping class."

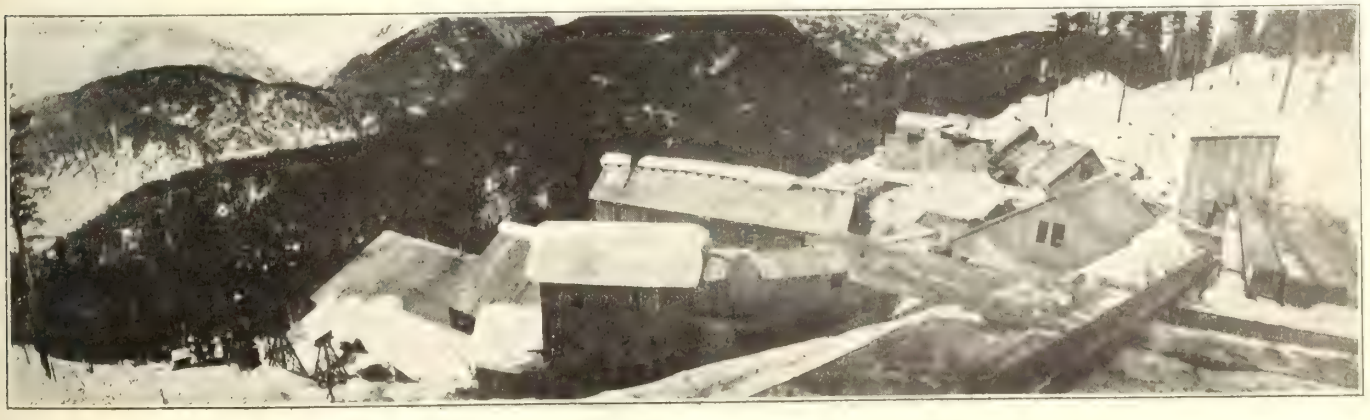
Leading the Way

Safely piloted by the Premier, the group of properties herein officially reviewed has progressed during 1923. Recognition of the vertical limitations of the high-grade horizons has not detracted from the value of the large milling-grade sections. Managing Director Guess in his annual report for the fiscal year 1922 stated that the Premier ore section has widened at depth. There remained in the ore reserves to the lowest working level of that time, 375,000 tons with an estimated gross value of $9,781,960, besides a satisfactory treasury. Model accounting evidenced the thoroughness of the business methods employed. Admitting that the average value of the ore was lower, it was pointed out that the ore reserve estimate applied only to the mine as it existed, not as it might be after further development. On the bottom level the average value of the ore dropped to 0.32 ozs. gold and 5 ozs. silver, nearly $10 per ton. Six diamond-drill holes had cut the ore-body level and indicated that this grade of ore continued to at least a further 100 feet vertical. Mr. Guess explained, however, that there was some 600 feet of unexplored ground to the eastward, along the same ore zone, and that there were possibilities southwestward of the same zone, to say nothing of what there might be to the northwestward and connected with surface showings to the south, on the Cascade No. 8 and Pictou claims.

More Ore Located in 1923

With the information in their possession, while proceeding with mining and development operations throughout 1923 upon a full tonnage basis, the Premier Company succeeded in extending the main ore-body for a distance of over 800 feet on the third level. Mr. Guess is authority for the statement that with a view to enlarging their mine, the company acquired the True Blue, Premier Extension Nos. 1, 2, 3 and 4, Extension Fraction, Mist Fraction, Mist No. 1, and 2, Bluox, Joe Fraction, Paul and Gloria Fraction, as shown by the shaded portions of the map printed herewith.

The object of these acquisitions, is evident. The Company owns about 38 per cent. of the B. C. Silver Mines, Limited, controlled by the Selukwe company. To explore the territory to the south of the Premier mine, situated on Cascade No. 4 and 8, and to reach the orebodies indicated by the outcrops on Cascade No. 8 and the Pictou, a drift is being carried on the 4th level southward, with a distance of 1,800 feet to its objective. At present this drift is 1,000 feet long. To the northwest, in the valley of Cascade Creek, a tunnel has been started from what was known as the Bunting tunnel. This is designed to explore the possibilities of the area from Cascade Falls Claim No. 1, southeast to the main workings. Boxing the compass, therefore, the Premier company is reaching for ore in large enough quantity to feed the new mill, which, Mr. Minor C. Keith is quoted as saying, will have a capacity of 1,000 tons daily. The Bunting tunnel extension, or No. 6 tunnel as it is designated, will be about 500 feet below the 4th. level of the main workings. It is now in



Surface plant of Premier Mine, looking down on the upper terminal of the aerial tramway, eleven miles long to the coast at Stewart. In the background are the hills on which are the Indian and Big Missouri properties.

about 800 feet, and going forward at a record rate of about 250 feet per month. With sufficient territory to protect mining and milling requirements, it is to be noted that the Premier Company has no connection with any other properties in the Salmon River District, excepting the B. C. Silver. It holds an option upon the Northern Light group, upon which it has been doing some surface prospecting during this year.

Premier's Dividend Record

Beginning in 1921, the Premier company has distributed $4,450,000 in dividends, has financed its affairs, has entered upon the development and exploration plans as outlined, and will build another concentrating and cyaniding mill. The present mill has a monthly capacity of 4,000 tons. The aerial tramway's monthly capacity is 10,000 tons. It remains to be seen whether this haulage system will be at all adequate. Bearing in mind that there was approximately $10,000,000 in the main workings a year ago, that a large tonnage of lower grade ore was indicated, that extensions of the richer zone in the upper level were anticipated, the Premier company output and what is in sight may be said to be over the $25,000,000 mark. The new mill will be located at the portal of the Bunting or No. 6 tunnel, about midway between the main workings and the Indian Mines. It may be that the production and dividend performances will not be so exceptional in the future, but there is no doubting the purpose and the confidence of the company. The higher grade ore in the upper horizon will sweeten the large tonnage of lower grade, and it is reasonable to suppose there will be more of the better grade found as development proceeds n the groups of claims owned by the company.

Significance of Strategic Moves

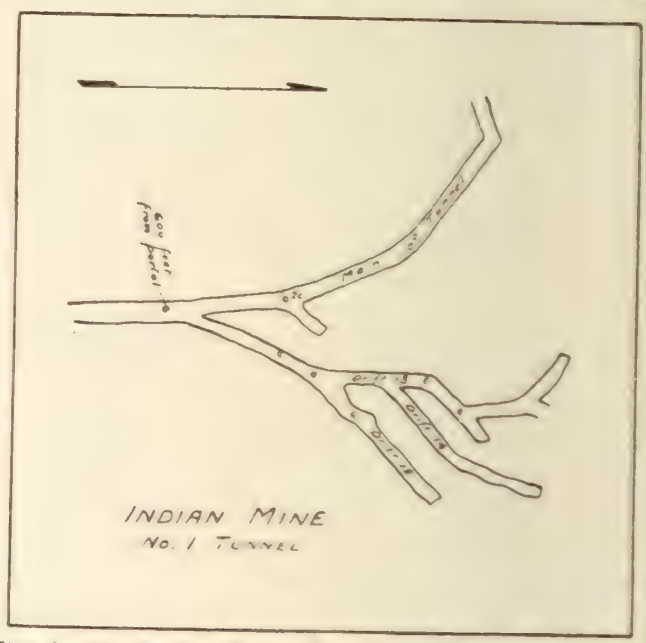
The ground taken over by the Premier Company during 1922 leaves nothing in the immediate vicinity to others, excepting the B. C. Silver properties due north of the mine, and the Indian to the northwest, across Cascade Creek. As about 38 per cent. of the B. C. Silver shares have been acquired by the Premier, the possibilities contained in Cascade Falls Claim No. 5 and in the Oakville Fraction that corners on to the Premier mine on the northeast, are fully realized. North, south, east and northeast. the Premier has all the territory it can handle for a good many years. Whatever is in the same geological horizon and concentrated near-by, the company possesses. in whole or in part. Between the portal of the No. 6 tunnel on the north and the Pictou ground on the south, explorations are being extended for a distance of four thousand feet. the Premier mine being in the center.

The property is receiving the comprehensive treatment it deserves, while the B. C. Silver company is endeavoring to prove up an extension of a Premier ore-body. The Premier zone is ample for these large operations. The nineteen mineral claims and fractions owned a year ago now have been increased to thirty-two, a fact that conveys its own significance. Reference to the shaded portions of the map will bear out the conviction prevailing that the Premier company entertains no half-way measures.

Indian-Big Missouri Situation

Having a fixed, productive standard in the Premier, eastern Canadian interests in the neighborhood naturally are greatly encouraged by the latest disclosures at the Indian Mines and reports concerning the Big Missouri. The narrow valley of Cascade creek intervenes between the Premier and the Indian, and to the north of the latter is the Big Missouri, now held by the men who enlisted the Guggenheim-Keith-Untermeyer group in the Premier. Manifestly the Indian is in excellent company, and the Premier-Big Missouri aggregation is understood to be not at all ashamed of what is transpiring at the Indian, where some of the better grade of ore as stated by the management compares with the best there is in the district, and where the tonnage of milling grade being put in reserve thus far confirms last year's prediction by Mr. Clothier. Undoubtedly the Indian has been fortunate in finding a section of very good ore.

Though Cascade creek separates them, the Premier and the Indian are believed to have similar geological conditions and all the evidences of those crustal movements which justified the participation of influential capital. Recent reports give the Indian both widths and values. No longer can it be contended that the Indian does not possess a share of the favorable quartz porphyry horizon. It is too soon and it would be misleading to classify the Indian as a first dimension mine, comparable with its neighborhood: but it is due to the Clothiers and and their Montreal and Toronto successors in the ownership of this and other properties in process of being acquired, to state that they feel they have most substantial reasons for providing the money needed to prove their extensively mineralized zone. The complicated fissures, the size and nature of the lenses characteristic of the Premier-Indian Big Missouri section, the values and structural variations have exacted "a cautious policy of exploration and development" that has now resulted in the decision to enlarge the scope of operations.



This fan-like section indicates the width of the Indian Mine zone and its possibilities, taken in conjunction with outcrops above a point several hundred feet ahead of these workings.

Indian Corporation Holdings

Fifteen claims and other fractions constituting a solid block are owned or under option. Until the advent of the Montreal and Toronto interests, Indian Mines Corporation held four crown granted claims. Developments on the Portland claims, the outcrops on the Boundary and Morn claims, the prospects elsewhere, prompted the more ambitious operations that now have been awarded. A large zone and longer lines of outcrop are being determined by aggressive underground work and by diamond-drill.

Altogether about 3,500 feet of tunnels, drifts, raises and crosscuts have shown that the zone and its fissurings are persistent for a known lateral distance of at least 1,200 feet at this writing. The intensely fractured zone as described by Mr Turner, "cuts across the general north 20 deg. west strike of the country." Bedded deposits

along the northwesterly strike, are an occasional feature. These Mr. Turner designates as the Northwest Series. To quote him further, and by way of explaining what the management had to solve, "cross fissures on a strike of north 30 deg. east, intersect and cut through the North-South and Northwest Series, but are frequently obliterated at the crossings through a subsequent movement along the North-South vein system."

Aspect Altered in a Year

To ascertain this and to intelligently comprehend the structures as a whole, while putting enough ore in sight to provide optimism, entailed capital expenditure and persistence. Outcrops a'plenty were prima facie evidence. Three tunnels, for a while, did not clarify the situation; even now there is a great deal to learn. A year ago it was recognized that ore-bodies in the workings did not correlate with outcrops. According to Mr. Turner, there was enough in prospect, if not actually proved on the tunnel levels, to warrant the statement by him that the Indian mineralized zone is over 150 feet wide, and that it "can

Portal of Indian Mines tunnel showing main vein

be traced for at least 3,000 feet." A possible outcome of the expenditure of what working capital there was on hand, was 110,000 tons of ore estimated at $1,995,080.

At that time the porperty was not beyond the debatable stage. The lower tunnel and the main tunnel had various lenses averaging $18. Crosscuts indicated other ore-bodies or lenses. It was decided, therefore, to provide more ample working capital, to push the lower tunnel and also to concentrate in No. 1 tunnel, the upper one. Thus far, his decision has brought additional results, which Mr. Turner describes as follows:

"The ore-bodies are all replacement deposits in lenticular form and are found in all the veins, but generally at the intersections of the various fractures or fissures. In No. 1 tunnel, an almost continuous ore-body was extended along a distance of 400 feet from the portal of the tunnel to the No. 13 station but this, properly speaking, is a series of closely-connected lenses."

The accompanying sketch of No. 1 tunnel, showing where the series of veins fork as it were, illustrates the position confronting the management. Of this, Mr. Turner says: "Near the end of No. 1 tunnel all the vein series of different strikes come together. It is here that the best conditions prevail, as shown by the large ore-body being explored from No. 1 tunnel."

It is to be explained that this special reference is to the development in what is known as No. 13 drift: "An average sampling across 26 feet assayed $25 per ton, and other samples point to this average value. This new ore-shoot is explored for about 175 feet in length. Assuming that it will extend to the surface, or near to it, and be of the same thickness and average value, there would be 66,000 tons in the block of ore which, at $25 per ton would contain a gross value of $1,650,000 between this upper tunnel and the surface."

These computations are based upon progressive developments and the line of outcrop. Mr. Turner qualifies them by writing: "I am only giving these figures in order that you may have some idea of the importance of this new strike, and while the ore is not blocked out, this tonnage, on the strength of the evidence seems reasonable, especially as I have made no allowance for the ore going below the No. 1 tunnel, until it is actually drilled and development completed."

While the projection is thus qualified, it is urged that another similar "condition of vein intersection exists on the surface, 400 feet in advance of the present face of No. 1 tunnel"; and other "occurrences of this kind are likely to be met with" under the present plan of development. Included in this plan is the pushing ahead of the tunnel and related drifts, while a series of drill-holes will determine the whole section along to the north. The relationship of the outcrops in this area to the north of the one that is undergoing development, calls for the combined development and drilling campaign; for the Morn area, further north, and the Boundary claims, have outcrops with widths and values deserving attention before the freeze-up. One outcrop on the northerly extension, traced for 270 feet, is said to be 12 feet wide, and averaged $15.

This much having been accomplished in a year, with a section so varied yet offering ore of profitable milling grade, it will be admitted that more could not have been done with the plant available. There is approximately 200 feet of back from the No. 1 tunnel level, and the vein system traverses the main Indian area and extends into the Morn. The diamond-drill and machines underground are expected to make the upper section of the Indian, together with what is exposed in the lower tunnels at date, ready next spring for the mill that is under consideration. Possibly the tunnel can be carried along fast enough to confirm the values at the outcrops, to enable the directors to avail of the winter roads to haul in some of the milling equipment. Certainly the Indian will require a larger power plant to deal with its expanding mining position.

Meanwhile the Big Missouri development is proceeding. Diamond-drilling has located a large section of ore averaging over $20. How much more there is of it has not been stated publicly.

LIFE OF THE RAND

In an statement recently published, Sr. Robert Kotze, Government Mining Engineer, estimates that in 1927 the Rand will be producing 31 millions sterling per annum, and in 1932 the amount will have fallen to 29 millions. The present rate is 37½ millions. These figures involve a decrease of 23 per cent. in ten years.

During the past ten years the imports of kerosene into Finland have decreased thirty per cent., due to the increased use of electricity for lighting, and this in spite of an extension of its use in oil engines.

Undersea Coal Mining in Nova Scotia

Longwall Method Giving Good Results and is Safe and Economical

By JOHN MOFFATT

The success of undersea mining in Nova Scotia was assured long before the public began to realize that there was much of it being done. When it is stated that seventy per cent. of the yearly output of Nova Scotia is drawn from the undersea areas it can be easily understood that the problem of taking coal from under the ocean in Cape Breton is well on the way to a successful solution. Indeed it can be asserted with confidence, backed by proof sufficient to satisfy leading mining engineers, that under-sea mining has long passed the experimental stage, when doubt was entertained of its success and danger of the inrush of the sea was never absent from the mind. The very fact that over 4,000,000 tons of coal were produced from this source during the year and larger outputs are included in the estimate for the coming year, places the matter beyond all question.

The rim of the coal field only is exposed on the coast and is studded with collieries, from which will be drawn at least ninety per cent. of the future output of Nova Scotia. The beds themselves, apart from this narrow edge, are under the sea.

Quality of Coal Improving. — We are not, however, oblivious of the fact that difficulties may be met as this great coal field is developed, which may add seriously to the problems of mining. But up to the present all geological indications and all correlated evidence point to a great unbroken coal field stretching far out under the Atlantic Ocean's bed. All the faulting found on land has disappeared there, and the most advanced workings show uniform strata and regular coal seams, with an increasingly fine quality in some directions, which confirm the opinions of the well-known mining engineers handling this most interesting problem. That there is an almost limitless supply of undersea coal, and that with due care of the entrances now being made it will be safeguarded for future generations, is the belief of these men, whose privilege it is to develop and conserve it in the interests of the province.

Slopes are Well Protected.—It was recognized from the very beginning that much of the coal of Cape Breton Island lay under water and plans were made to give the greatest amount of protection where the workings entered the sea areas. Here the cover is the lightest, and here might be expected the greatest cause of danger, namely rock fracture, or holes reaching far down due to deep erosion in old river beds. The coast waters were all sounded carefully and a knowledge of the ocean bed ascertained. These were found to be shallow within a twelve-mile radius, with rock bottom forming ledges here and there. The large pillars left to support the mine in the early stages when land was left behind greatly reduced the quantity of coal extracted, but these will all be won on the way back, after they have served the very useful purpose of protecting the coal seams at the weakest points.

The courage displayed by the mining engineers of Nova Scotia is well demonstrated by the fact that in one of the more advanced collieries the bord and pillar method of mining has been discarded, and longwall mining introduced. This system is giving good results and ninety-five percent of the coal in the seam is being won. The pillars of a colliery at Sydney Mines having been extracted without untoward results though it was two miles undersea, it was found by actual practice that the system most suitable to these coal fields would be one by which all coal could be taken out at once. This tends to let the measures between the seam and the bed of the sea settle or subside uniformly. As the overlying strata are impervious to water, it was early discerned that the method of mining most successful must avoid rock fracture, and bring on a gradual subsidence.

Longwall Undersea First Tried by T. J. Brown. — The present Minister of Mines, T. J. Brown, was the first to prove this point in Nova Scotia, and he was most successful in drawing the pillars of the famous old Princess Colliery. Since then other engineers have followed his example. The collieries of the Glace Bay district are still in the pillar-drawing stage, but even this method more than doubles the quantity of coal extracted in the early stages of undersea mining. With thicker cover, the longwall method will become universal and as the collieries advance all coal will be taken out. By this method the ocean bed can be lowered without danger of rock rupture, and with a maximum amount of safety to the mine.

Hydraulic Stowage not Required. — The longwall method of mining precludes all necessity for hydraulic stowage and saves the extra expense entailed. Indeed, it is impossible to adopt this system in a coal field lying on an flat angle of inclination miles under water, and in this competitive age no other system, such as filling with waste from mine cars, could be attempted. In the thick, steeply pitching seams of the Pictou coal field hydraulic stowage might no doubt be a success under certain conditions; but the time has hardly arrived in Nova Scotia when it can be put into operation at a profit.

With the necessary protection at the openings of this vast coal bed, the improved methods of mining under thicker cover, the partial electrification of all the collieries, the introduction of the most modern mining machinery, the ever increasing price of coal, the impetus of a great and progressive corporation, and the universal recognition of the natural geographical advantages of the coal fields of Nova Scotia, the future prospect of the mining industry is most pleasing. "The best is yet to be," and the near future is bright with the promise of good things foreshadowed in the minds of those directing the destinies of coal mining in Nova Scotia.

DOMINION PETROLEUM AND GAS REGULATIONS

The Mining Lands Branch, Department of the Interior, Ottawa, has issued a revised edition, superseding that of November, 1922, of the Regulations for the disposal of the petroleum and natural gas rights in the provinces and other areas under its jurisdiction.

Huronian Belt Company's Annual Report

Satisfactory Year for Company that Holds Keeley and Vipond Stocks and Numerous Undeveloped Mining Claims

On October 8th the annual meeting of the Huronian Belt Company was held in London. In presenting the annual report to the shareholders, the chairman, Mr. T. H. Hamilton said:

The report and accounts before you reflect a highly satisfactory position.

If you will turn to the balance-sheet you will observe that your only liability, apart from capital, is sundry creditors, £11,207. On the other side we have sundry debtors, which represent shares sold and not delivered and undistributed balances £20,639, cash in London and Canada £35,200. Since the close of the accounts a further £15,478 has been received in respect of calls on shares. The other item on the asset side of the balance-sheet, cost of shares and interests, £66,357, calls for some elucidation. It represents, among other things, over 100,000 shares in the Associated Gold Mines of Western Australia, Ltd., between 60,000 and 70,000 shares in the Keeley Silver Mines, Ltd., and between 60,000 and 70,000 shares in the Vipond Consolidated Mines, Ltd., besides certain Canadian shares which are not dealt in on the London market. It also covers your properties, which, you will observe from the details given in the directors' report, are considerable both in size and importance. That is a very strong position, on which we may fairly congratulate ourselves. The balance of profit for the year, £26,761, is subject to income-tax, corporation tax, and 5 per cent in favour of the directors. This it is proposed to carry forward.

Developments on Vipond And Keeley Mines

The developments on the Vipond and Keeley mines have been published in the Press from time to time, and I need only make passing reference to them. As you know, they have been eminently satisfactory. At the Vipond the vein known as No. 10 has been opened up during the last few months at the 400 ft., 500 ft. and 600 ft. levels, giving high values over great widths. The Vipond, as you know, adjoins the Hollinger gold mine, and although we have only been at work on the No. 10 vein during the last six months Dr. Mackintosh Bell reports that over two years' supply of ore, averaging over $10 per ton, is in sight, without reckoning a large amount of lower grade stuff. The work now proceeding continues to open up high grade ore, and the mill, which has a capacity of 150 tons a day, is timed to commence production during December next. It is too soon to attempt to estimate the exact significance of these recent developments, but, having regard to the fact that they only apply to a small portion of the company's area, they must be regarded as extremely satisfactory and encouraging.

The South Lorrain Field

The remarkable results obtained at the Keeley mine during the last eighteen months have drawn attention from all parts of the North American Continent to the South Lorrain field. This company, as you know, was not only the sponsor of the Keeley mine, but it was due to its work in the first place that the rich possibilities of the district were recognized. As you will see by the directors' report, we have not been idle in South Lorrain. We have interests in H. R. 22, an area immediately adjoining the Keeley mine on the west, and in H. R. 610, about 1 1-4 miles to the south, but we have to a large extent concentrated work upon a property known as the "Maidens," situated some three miles north of the Keeley and less than half a mile west of Lake Timiskaming. The property comprises H. R. 66, 67, 69, 70 and 72. I quote the official references and numbers of the claims, so that shareholders can identify them for themselves on any map of the field. Some work was done by the previous owners, and four strong veins, showing in places good silver values, have so far been discovered on the property. We have done a good deal of work during the past summer, mainly of a preparatory nature, cutting roads, putting in plant, etc., and actual mining work is only now beginning. The results of that work during the next six or nine months will be of very great interest and significance, not only to us, but to the whole South Lorrain field. The theory, of course, is that we are dealing with a similar proposition to the Keeley, and that we may expect a zone of great enrichment when we approach the contact of the diabase and keewatin.

Energetic Development Programme Justified

The point is one upon which I offer no opinion of any value, except to say that Dr. Bell's considered estimate of any South Lorrain proposition must carry the greatest weight. In the course of the report, to which reference is made in the directors' report, Dr. Bell sums up the position with regard to this property as follows:—

"It seems unreasonable to suppose that the four principal veins so far discovered, and the various minor veins, represent all the property contains; it is altogether probable that others will be discovered during the progress of the sub-surface operations. The known veins are limited to keewatin rocks, and have been opened up only at what is thought to be a considerable distance above the diabase-keewatin contact. At such shallow horizons the silver content should theoretically be much less than at deeper horizons nearer the contact. Yet even at this distance at least one vein (No. 1) shows a substantial silver content, which increases in amount downwards. The chances for the discovery of shoots of silver-bearing cobalt ore of commercial size, when development has been carried out at favorable horizons, at or near the diabase-keewatin contact, are excellent. I believe the implications amply warrant the carrying out of an energetic development programme."

New Interests Acquired

To that restrained opinion I need only add that the Board attaches such importance to the company's holding in the "Maidens" that it has, on Dr. Bell's advice, acquired interests and options in the surrounding properties H. R. 509 and 520, and T. 19, 262 and 19,263, so that if the theory upon which we are working proves correct we shall be controlling a very large area.

Our interests outside South Lorrain include a three-fourths interest in three claims next to the Murray Mogridge gold mine, and two claims in the Rouyn township district on the Quebec-Ontario frontier, a goldfield which is in its infancy, as the first discoveries were only made last year shortly before the snows commenced. Work during this summer in this field has been exceedingly encouraging, and at one or two points deposits have been opened up at or near the surface which would appear to be of great promise.

We are also shareholders in the Noranda Syndicate, controlled by an American group, which is the largest

claim-holder and, in a sense, the pioneer of the district. The latest reports from the Noranda Syndicate, which came to hand last month, would appear to justify the expectation that a great deal will be heard of thiis district during the next twelve months.

We are also considerable claim-holders in the gold-mining district of Sault Ste. Marie. We have not given detailed particulars of our holdings in this particular field, partly beause full reports have not yet come to hand, and partly because our work there has not yet come to an end. It is too early to pass a definite opinion on the strength of surface prospects, but, as the directors' report states, Dr. Bell has a very good opinion of its chances, and we are devoting a good deal of attention to it before the winter sets in.

The Company's Financial Resources

From this brief survey of our holdings you will see that they are considerable in point of area, and they are the outcome of investigation and examinations conducted systematically over some years. It is satisfactory to know that the resources of the company are commensurate with its properties.

You will realize from what I have already said that the position to-day is that, when the whole capital of £200,-000 is issued, the balance of cash and liquid resources, including only shares dealt in on the London Stock Exchange, will exceed £250,000. That is a somewhat exceptional position, especially having regard to the money we have expended upon exploratory work on properties since abandoned. It reflects, as most of you know, the results of some years of hard work, and is due, of course, in part to the fact that this company started as an exploration company, with no promoters to consider, and its capital, practically in its entirety, was represented, in the first instance, by cash. I need not point out that this question of financial strength is of great importance to a company of this character. This is not in any sense of the word a holding company, although we shall, no doubt, from time to time hold considerable numbers of shares. Our work is primarily that of acquiring the control of promising properties in Ontario, or elsewhere, in their early stages, of bringing them to the point of development at which we can obtain participants on profitable terms, and distributing those profits to our shareholders in specie or cash, or in both. This does not necessarily involve any large expenditure, but it may do so, and it is an enormous advantage to know that you can pursue your programme independently of market fluctuations or conditions, and if need be, independently of other partners.

Staff and Organization

I feel I should say one word regarding our Canadian staff and organization. Our work is, of course, to some extent seasonal. In the spring, summer and autumn, when the snow is off the ground, it is largely taken up by examinations of prospects, and in the winter, when that is not possible, by actual mining work. I believe that in both these branches our staff is second to none. In our managing director, Dr. Bell, we have not only a brilliant geologist, but a very capable organiser and he has under him young and highly-trained engineers who know the country and its conditions and who are ready at short notice to go to any point of the compass that offers the promise of attractive business. They have, as you can see from the report, not been inactive, and we have during the last few years accumulated a mass of data, some of a positive, and even more of a negative character, which, however, is scarcely less valuable. I think I can say two things with confidence. One is that the mining developments in Canada, and particularly in Ontario, wil in the course of the next few years attract increasing at tention the world over, and the other is that you have a staff, both on the business and on the mining side, com petent, efficient and active, which is eminently qualifie to play a useful and profitable part in those developments I feel sure that I am echoing your views in expressing our appreciation of the work that has been, and is being done.

LIQUID OXYGEN EXPLOSIVE IN COLORADO

Liquid oxygen explosive has been successfully used in Colorado in experimental mine blasting and road construction work at a cost of approximately one-half that of the gelatin dynamite required to do the same work. The experiments were conducted by E. D. Gardner, mining engineer of the United States Bureau of Mines, in co-operation with a representative of the Compressed Air Corporation.

A liquid oxygen explosive consists of gas black, wood pulp or some other carbonaceous material made up into cartridges and soaked in liquid oxygen. . This explosive can be detonated similar to ordinary dynamite with cap and fuse or with electric detonators. The liquid oxygen was obtained from a plant designed to furnish oxygen gas and was shipped to the point of use in Dewar flasks, which are made on the same principle as thermos bottles. The first Colorado tests made by the Bureau of Mines were conducted with cartridges made in Germany, but later cartridges manufactured at less cost in Denver proved very much more satisfactory.

As the use of this explosive is new in this country numerous tests and experiments were necessary to find a low-priced carbonaceous material which would have the desired qualities and to learn the technique of blasting with this new material.

Hand steel holes were blasted in granite on a road construction job above Idaho Springs, with results similar to those obtained with 40 per cent gelatin dynamite. Trees were also cleared from the right-of-way and a 200-ton cliff blasted down successfully. . Instantaneous electric detonators and blasting battery were used for this work and no misfires occurred and no holes failed to break properly. The oxygen was taken to the job in an automobile and the quantity not used was taken back to Denver. The small-sized cartridges were made on the ground from German material.

Regular drift rounds were blasted on the 200 level of the Yak mine. The oxygen was expressed from Denver and a cartridge developed and made at Denver was used. Eleven and 13-hole rounds, 4 to 5 feet deep in a 7 by 8-ft. drift, in firm limestone, were successfully shot with the liquid oxygen explosive. The rounds were loaded and blasted by two men in 8 to 12 minutes, which was well within the life limit of the cartridges. The blasts were made according to the standard practice in western mines with time fuse and caps. The rounds were broken clean in each case and the broken material was finer than was blasted with 40 per cent gelatin dynamite. Disregarding the express charges on the oxygen, the cost of this liquid oxygen explosive was about one-half that of the gelatin dynamite needed to break the same round. As far as is known, these are the first blasts of regular drift rounds made in the United States.

Besides costing less, the liquid oxygen explosive is much safer to use than ordinary dynamite. There are disadvantages resulting from its use, however, and much is yet to be learned before it can be universally adopted in metal mines.

WORLD'S COPPER CONSUMPTION

Speaking before the American Mining Congress in Milwaukee, Wiliam A. Willis, manager of the Copper & Brass Research association, said that partly as a result of work of the association in the last two years there has been an increase in domestic consumption of copper of at least 75 per cent.

"Of course," he said, "the full fruits of the campaign will never be felt until the situation abroad improves, because it must be remembered that the American copper industry was built up to its present proportions on the basis of a certain fixed foreign demand. This foreign situation seems to be gradually improving. but there can be no question it is primarily responsible for the low price of copper over the past few months, in the face of so hugely increased a domestic consumption.

"During the last eight months world consumption of new copper was approximately 230,000,000 pounds a month, which is at the rate of 2,750,000,000 pounds a year. Of this monthly consumption 192,500,000 pounds was supplied by American mines and refineries. These figures show that despite European conditions consumption over the eight months mentioned has been within about 10 per cent of war peak and more than 12 per cent above the pre-war world rate.

"August consumption of copper was the largest for any month of the year and was actually in excess of production. It can be seen from all of this that the copper industry is in a reasonably healthy state and that with the recovery of Europe it should not be long before the metal is bringing a price commensurate with the cost of production, making possible a fair return on the capital invested."—Iron Ore.

MINERAL DEVELOPMENT TO STIMULATE EMPIRE MIGRATION

In discussing Empire migration in a recent issue, the "Mining Journal" of London remarks:

"In the past, mining enterprise has been the most effective agency for inducing immigration into new countries: Australia, New Zealand, Kimberley, the Rand, Rhodesia, California, owe their start in life almost entirely to mineral discoveries and the lure of fortune appealing to individuals of every class of our population. But the appeal was not made by the mining industry generally; it was the lure of the precious metals, gold and silver, and of the diamond the prospects of finds which might bring affluence to the individual whose capital was little more than good health and good fortune, which produced the immigrations of the 'fifties, 'sixties, and 'seventies, and created the class of adventurous prospector which so powerfully supported mining in Colonial fields in subsequent years, and which is now exhausted. Modern mining is generally on a far vaster scale, involving low-grade ores, large capital, and employment underground, differing but little from what is available in established mining centres everywhere. Moreover, the prospects of gold finds are not what they were, and mining is largely of the base metal order, intrinsically far less attractive to the individual adventurer. The field of immigration, too, is narrowed by restrictive measures such as that imposed in the United States, and in a lesser degree in most of the Dominions. Spontaneous emigration of this type postulates the discovery of new mineral fields, which is precisely what has been conspicuously lacking of late years. If we have to rely upon constructive efforts to develop mining in the Dominions, we confess that we shall be curious to learn what is proposed. General Smuts suggests that we should buy our copper in Africa, more especially apparently from Tanganyika. How it will benefit this country to buy Belgian rather than American copper we do not know, and these are the only two sources from which the metal can be produced at the present time at current prices. A preference for Empire metals is a very attractive idea, but, considering the necessity of maintaining our export trade, we cannot imagine how it is to be organised or made really effective without cutting very severely at existing business undertakings, and through them at employment.

CYANURIC TRIAZIDE AS DETONATOR

Tests of the detonating properties of cyanuric triazide, made by the Department of the Interior at the Bureau of Mines experiment station at Pittsburgh, developed that this compound is a very efficient detonating agent, but is too sensitive to handle safely in large quantities. It is especially sensitive in the form of large crystals such as may be formed from fusion or re-crystallization. It is non-poisonous, but the materials used in its manufacture are irritating and poisonous.

Cyanuric triazide was discovered and patented by Erwin Ott, and on account of his claims, the Bureau of Ordnance, U. S. Navy, desired more complete data, so an investigation was made by the Bureau of Mines. The results obtained were such that the Bureau of Ordnance recommended publication thereof for the benefit of the explosives industry.

Cyanuric triazide is insoluble in water and slightly soluble in cold ethyl alcohol, but it is soluble in acetone, benzene, chloroform, ether, and hot alcohol. It melts at 94 deg. C., and there is decomposition when heated above 100 deg. C. In the molten state it is very sensitive to friction. If heated slowly, it may entirely decompose without detonation, but detonates quickly by flame or sudden heating. The small crystals are more sensitive to impact and friction than mercury fulminate and have detonated when being pressed in a detonator capsule. The large crystals, such as may be obtained from fusion or recrystallization, have detonated when broken by a rubber policeman.

Serial 2512, "Preparation and detonating properties of cyanuric triazide" by C. A. Taylor and Wm. H. Rinkenbach, may be obtained from the Department of the Interior, Bureau of Mines, Washington, D.C.

TIN IN NIGERIA

For the three years 1919-21 Nigeria exported an average of 8,000 tons of tinstone. The mineral was found to occur in the Protectorate only recently, and a prompt investigation, on the initiative of the Imperial Institute, resulted in its discovery in numerous widely separated localities, while workable deposits were found in the northern provinces.

Quebec's Water Powers and their Relation to Other Natural Resources

As an indication of the good work of education and propaganda being conducted by the agency of radio, we print the following broadcasted recently from Montreal by Dr. W. G. Kennedy:

The potential and actual wealth of the Province of Quebec, is vast and varied; the forest, the mine and the water power, each in its turn is among the largest of its kind in the world, and each is a source of development and prosperity complete in itself.

It is of the immense water powers of the Province I would speak to-day, the development of which, measured in electric energy, is such as to make it possible for the Province of Quebec to become one of the large industrial centres of the world.

Distributed throughout the Province are sufficient waterfalls and rapids to generate approximately 15 million horsepower in electricity. There is no other area in the world of like size that has such vast potential hydro-electric powers and the very fact of their wide distribution reduces the cost of development and distribution to a minimum. For instance the City of Montreal receives the whole of its electric supply from within a radius of seventy miles, even though there are three sources of supply.

"White Coal"

To date about one-fifteenth of Quebec's water powers have been developed, or to be exact, 1,078,883 horse power. This amount of electric energy means the economical running of many industries, the efficient public lighting of many cities, towns and villages and the supply of illumination to hundreds of thousands of stores, homes and farms, at prices much less than in the days of the tallow candle, the paraffin lamp or gas. The harnessing of her waters has brought much comfort and benefit to Quebec's people. It is calculated that the developed power of the Province is equivalent to the burning of 8,000,000 tons of coal per year. As the Province of Quebec has no coal beds of its own, all the coal used must be imported. This means that if science had not shown us the way to utilize our white coal as a motive power, the province would be in a sorry state indeed. The great industries of our cities, and towns, the pulp and paper mills of our outlying districts would still be merely a dream, for the cost of motive power would be prohibitive.

The industrial development of the Province is the direct result of, and depends almost entirely on its water power development. The one keeps pace with the other, and no more.

Terms of Lease

The development of the water powers of the Province is partially the result of private enterprise, and partially the result of governmental activity. Up to the year 1884 water power sites were sold outright and many waterfalls passed into private hands. In that year the Government passed a law which reserved to the Crown a width of 200 feet along all non-navigable rivers. As the water-powers became more valuable the Government imposed stricter conditions on those who acquired them, and also demanded better prices. For instance, Shawinigan Falls under the new conditions of that time, were sold for $60.000, with the proviso that three million dollars be spent in their development. This condition of course has been carried out in its entirety.

In the year 1909 the Government introduced a system of leases to take the place of the old system of sales. That is, instead of selling a water power outright, the Government leases it for a period of 99 years Under this system, the lessee, after fulfilling his obligations, becomes to all intents and purposes the actual proprietor for the duration of the lease. The lessee can mortgage or sell the property and make and enjoy any improvements he likes; but at the end of the lease, the lessor, or Government, takes back the property and all the improvements made thereon. In this way, while the lessee enjoys special privileges, not granted in an ordinary lease, the people remain the owners of the site for all time.

These are the conditions that govern the development of the Cedar Rapids of the St. Lawrence River, and those by the Southern Canada Power Co., on the St. Francis River. As an indication of the intrinsic value of the water powers to the Province, I might say that the rentals from leases and from the Government storage reservoirs amount to more than $300.000 yearly.

Storage Dams

The governmental activity in the development of the Provincial water powers has taken the form of the construction of dams so as to insure a constant supply of water all the year around. For this purpose a special department was created in 1910, under the supervision of the Minister of Lands and Forests. A little later the Quebec Streams Commission was established, and it is this authority that has the control and regulation of all the rivers and waterfalls of the Province.

Under this authority the Gouin dam and reservoir on the St. Maurice river, the Allard reservoir on the St. Francis river, and the reservoirs on Brule Lake and Savane river, were built, and other works of vast magnitude are now under consideration.

The Gouin dam and reservoir, which is located at the head waters of the St. Maurice river, is the largest works of its kind on this continent. It stores more water than does the famous Assuan dam built on the River Nile by the British Government. Its water area is over 300 square miles and its holding capacity is 160 billion cubic feet. This development, which cost in the neighbourhood of $2,500,000, more than pays for itself. Last year the reservoir yielded a revenue of $212,459, from the four companies that use its stored water. After deducting interest on the capital expended and taking care of a sinking fund to redeem in thirty years the bonds issued to provide the cost of the work, a substantial profit is left over for the Government.

It is the waters of the St. Maurice river that provide the energy supplied to the Cities of Montreal and Quebec, and all the intervening towns and villages. From the power houses of Shawinigan Falls and Grand'Mère the power is carried to all these places by huge cables strung on steel towers.

The St. Francis river dam and reservoir has a storage capacity of 12 billion cubic feet, and supplies the many industrial establishments of the Eastern Townships.

New Works

The Streams Commission has now under contract the construction of a storage reservoir in lake Kenogami, so that the pulp and paper mills located at Chicoutimi and Kenogami may be insured a steady supply of power. Already 61,000 horse power has been installed.

Within the last few months the Government has entered into a new phase of power development. Contracts have been let for the utilization of the waters of Lake St. John and the north shore of the Gulf of the St. Lawrence. This utilization will mean two enormous developments, the one a minimum of 230,000 horse power at a cost of $12,000,000, and the erection of mills costing upwards of $15,000,000, and the other the operation of some of the great water-powers of New Quebec.

One might go on enumerating the different power developments of the Province, but I have quoted enough to show something of the tremendous range of our water powers, and their value in the development of the vast natural resources of Quebec.

TEST SHIPMENTS OF ORE TO OTTAWA

In the past those shipping ore from the West to Ottawa for tests in the laboratories of the Division of Ore Dressing and Metallurgy of the Mines Branch, under the direction of W. B. Timm, have had the disadvantage of high freight or express charges. In order to equalize these charges somewhat as between east and west, the Department of Mines has included in its new regulations a provision that "freight charges in excess of 75 cents per 100 pounds, and express charges in excess of $4.00 per 100 pounds, will be paid by the Department of Mines. On car lot shipments proportional freight charges will be paid by the Department." For small scale tests not less than 100 pounds, and for large scale tests not less than one ton will be accepted. In cases where communication is difficult a shipment from 50 pounds to 2,000 pounds in weight will be accepted; from 50 to 200 pounds in weight it may be sent by either express or freight; above 200 pounds it must be sent by freight. All shipments must be certified by a resident mining engineer, a mining recorder or some other competent authority as worthy of being tested. On page 832 of our issue of October 19th, in correspondence from British Columbia, some of the above regulations were cited erroneously.

USE OF PREPARED NON-METALLIC MINERALS IN CANADA

The possibility of establishing grinding plants in Canada to produce the many varieties of finely ground non-metallic minerals used in Canadian industries is the subject of a comprehensive report prepared in the Mining, Metallurgical and Chemical Branch of the Dominion Bureau of Statistics. Heretofore, though extensive deposits of the crude material are known to exist in Canada and though these deposits are in certain cases being worked, the bulk of the supply has been derived from importations. It has been suggested that it is feasible to substitute Canadian products for certain of these importations, and it is the purpose of the report now described to present the data required for computing the probable extent of the substitute market which might thus be developed.

With the exception of sulphur in the native state, whiting and some special grades of clay, Canada possesses important deposits of almost all the non-metallics most commonly used in industries. The minerals now being consumed in Canada in the ground or prepared form are: actinolite, barytes, calcite, whiting, dolomite, corundum, feldspar, fluorspar, gypsum, lime, magnesite and magnesia, mica, iron oxides, quartz or silica, including silex and flint, tripolite, and talc. Of these, gypsum and magnesite are produced in considerable tonnages, are calcined and otherwise prepared in Canada and supplied in the ground form and larger sizes to consumers both in Canada and abroad. Talc is ground and produced in several marketable grades which are shipped to consumers throughout Ontario and Quebec as well as the United States. Lime is mainly used as crude quicklime in the building trades, pulp manufacturing, sugar and glass-making industries and a limited amount is used as lime-flour. Actinolite, quartz, feldspar and mica are now being prepared to a limited extent in Canada.

Copies of the complete report may be had by those interested on application to the Dominion Bureau of Statistics at Ottawa.

STRENGTH OF T N T

Trinitrotoluene is made by the direct nitration of toluene by a mixture of nitric and sulphuric acids. The exact procedure varies, but the product, where Grade I of TNT is desired, is similar, and consists largely of material that has a melting and setting point of 80.6 deg. C.

The purification consists of draining off the liquid portions, including the acid and liquid nitro compounds. The mass is crushed and washed until the TNT is acid-free. It may still have a low melting point due to the presence of material of lower nitration. Other insomers also have the same effect. The crystal mass may be washed with a solution of sodium sulphite, thiosulphate, sulphuric acid, or with an organic solvent such as alcohol, benzene, or carbon tetrachloride. Where a very pure product is desired, the TNT is separated by fractional crystallization from solution in organic solvents.

In some cases the material is melted during purification. The TNT is agitated as it cools to prevent solidification in a solid mass. If it forms in a solid mass, this is broken up and screened. There has been some question as to the effect of the different methods of purification on the strength and sensitiveness of TNT, although all methods left a product that would give satisfactory tests.

The results of experiments made by C. A. Taylor, explosives chemist, and R. D. Leitch, assistant explosives chemist, to determine the strength and sensitiveness of TNT, using the laboratory "sand-test" bomb, are given in Serial 2526, which may be obtained from the Department of the Interior, Bureau of Mines, Washington, D. C.

AIRSCREWS FOR MINE FANS

In a paper presented recently before the Chemical, Metallurgical and Mining Society of South Africa, Mr. F. A. Steart gave the result of an extensive series of experiments in the use of the propellor blades used in airplanes for causing a flow of air against a light head, as in mine ventilation. Though the experiments are incomplete, it has been shown that efficiencies comparable to those obtained with centrifugal fans are feasible with the use of these blades.

COAL OUTPUT IN JULY

The Dominion Bureau of Statistics' latest report shows that the output of coal from Canadian mines during July amounted to 986,400 short tons, a decrease of 25 per cent. from the tonnage for the previous month, and 14 per cent. from the average for the month of the three preceding years. The output for the month showed decreases of 435,000 tons in Nova Scotia, and 4,000 tons in New Brunswick. In Alberta there was an increase of 106,000 tons, in British Columbia 6,000 and in Saskatchewan 2,000 tons. The cumulative output from all mines for the seven months of 1923 amounted to 9,717,000 tons, an increase of 20 per cent. over the preceding three-year average for the same period.

Imports for the month from the United States and Great Britain were 2,445,000 tons, which is 58 per cent. greater than the preceding three-year average. The total importation of coal for the seven months of the year was 12,648,000 tons, an increase of 53 per cent. over the three-year average for the period. Evidently the people of Ontario and Quebec are commencing to take time by the forelock in their winter supply of fuel, both domestic and industrial.

The total number of men employed in the coal mines of Canada during July was 27,304 of whom 20,202 worked underground and 7,102 were surface men, as compared with 20,615 underground and 7,054 on surface in June. The production per man was 36 tons for July as against 47 tons per man in June. An examniation of the "Tonnage Lost" for July shows great losses in Nova Scotia due to labour troubles while the mines of the western provinces were again handicapped by lack of orders.

WHO PAYS FOR THE ACCIDENTS?

This question is discussed by Richard V. Ageton, Deputy Mining Supervisor of the United States Bureau of Mines, in Serial No. 2535, issued last month. From data collected by two large companies who carry their own insurance and maintain hospitals and medical staffs, the injuries are classified and the loss per injury computed. In both companies the majority of accidents occurred to the hands (including the thumbs and fingers); the eyes; and the feet and toes. In "A" Company, the greatest number of injuries occurred to the hands (including thumbs and fingers), with the eyes second, and the feet and toes third. In "B" Company, the hands (including the thumbs and fingers) were first, the feet and toes second, and the legs third. There are some differences, for instance it seems that injuries to the head and face in "B" Company were less costly in wages lost than in "A" Company. Also hernia is apparently less expensive in wages lost among employees in "B" Company than among employees in "A" Company, but this may be largely due to the fact that "B" Company employed a physician who had made a special study of hernia operations, and who is one of the foremost physicians in this line of work in the United States, consequently these men were able to return to work much sooner than the men of "A" Company.

It was found also that 48.1 per cent. of the injuries occur during the first two months of employment, and that 20.5 per cent. of the injuries occur during the first week. Therefore, many of the accidents occur before the man has become accustomed to the work in that particular mine. Consequently, if the work on a contract basis, as the majority of it was in these two mines, the man had not become trained enough to reach his maximum earning capacity, or to give the company full value for the money being paid him.

Every mine and every level or working place in the mine where a distinct kind of work is being done has its individual hazards, and should therefore be studied by the men working there, and by the boss in charge of that part of the mine. Such a study must be supplemented by studies of wider scope, insofar as hazards, apparently similar, may exist in other mines. Much can be done by the safety bureau and the medical department, if they work in close harmony with each other and with the individual miners. The entire mining industry will most quickly lessen the hazards of mining by keeping uniform accident records that will facilitate the scientific study of accident prevention by companies working individually or in cooperation with other companies and with local and Federal safety organizations.

ACTIVATED CARBON

Activated carbon has become an important metallurgical reagent, in addition to its uses in industrial chemistry and its original use in the gas mask. It is still prepared most successfully from the shell of the cocoanut, whose minute and multitudinous capillary pores present a very large surface to the reaction promoted by the contact of carbon and the gas or liquid being treated. In addition to its numerous commercial uses dependent upon its power to absorb gases it is used to condense the gasoline contents of natural gas and the benzol of coke-oven gas, to store gas, and as a catalyst. As a catalyst it is used already to convert hydrogen sulphide into sulphur and water, to accelerate the oxidation of nitric acid as much as 500 fold, and to promote the chlorination of hydracarbons. A cylinder filled with activated carbon will contain 66 per cent more nitrogen under a pressure of 35 atmospheres than the empty cylinder.

ORIGIN OF PETROLEUM

The origin of petroleum in nature is still undetermined. It might well have been formed from the vegetable matter that is now represented by coal beds, but for the fact that there is much more hydrogen in the petroleum than in the gases from the vegetable remains. Recent experiments tend, however, to support this idea. By exposing coal to hydrogen under a pressure of 5,000 pounds to the square inch, a remarkable exothermic reaction takes places that results in a fluid indistinguishable from crude petroleum. This opens up an interesting field for speculation as to the possibility of converting solid fuel to liquid fuel on a commercial scale.

THORIUM MINERALS IN CEYLON

Until recent years the world's supply of thorium came from monazite from Brazil, and was under the control of a German firm. Now thorium is being recovered from monazite sands in Ceylon, which afford a small annual supply. The discovery and investigation of these deposits has been due largely to the efforts of the Imperial Institute, which has an especial charge over the raw materials of the outlying parts of the Empire.

MOTOR FUEL FROM HEAVY OIL BY HYDROGENATION

In the August issue of "Fuel in Science and Prac-e," Mr. H. G. Shatwell writes on the "Hydrogena-n of Hydrocarbon Oils."

Mineral oils, containing as they nearly all do, cata-st poisons like sulphur and asphaltic compounds, do t readily lend themselves to treatment with cata-sts, especially finely divided metals, and it is for is reason that so much interest has recently been inced in the Bergin process of hydrogenation, hereby a catalyst is specially stated not to be used.

The Bergin method of hydrogenation consists in ating a heavy oil to a temperature of about 400 deg. for several hours in the presence of hydrogen, nder a pressure of approximately 100 atm. (1,500 s. per sq. in.). It is claimed that large yields of a veet-smelling, saturated motor spirit are produced d that the residue can be again hydrogenated to give still greater yield of low-boiling products. Further, e deposition of carbon and the formation of gaseous drocarbons are so slight that there is no difficulty elaborating a continuous system of treatment, while e Bergin process is also capable of dealing with pe-oleum oils which contain high percentages of carbon, d which, hitherto, have not been successfully acked.

This high-pressure method of hydrogenation has but cently emerged from the experimental stage. Much luable work on the hydrogenation of coal, lignite, al tar, and various hydrocarbons is being carried t by Fischer, Schneider, Schrader, and others at ülheim, Ruhr, while similar investigations are being ndertaken in this country, both from scientific and chnical consideration.

OST OF LOW-TEMPERATURE CARBONIZATION PRODUCTS

During a tour of inspection, one of the engineers of he Ford Motor Co., gave some interesting calculations ith regard to the Caracristi and Piron lead-bath low-mperature process being installed at the works.

He stated that they would be able to make gas for ½ c., instead of 50 c. or 60 c. per 1,000 c. ft., which as the production cost at present. In addition to this, hey would secure light oil, suitable for use as a gaso-ine substitute, for 7.3 c. per gall., and sulphate of am-nonia for less than 2 c. per lb. Further, there would e a heavy oil residue which would cost them 2.5 c. er gall., and could be re-distilled into a gasoline sub-titute for 6 c. per gall. There would be creosote oil or timber preservation at a cost of 7 c., and a heavy uel oil for 3.5 c. per gall.

The coke produced would come off in sheets at the ate of 25 ft. a minute. This sheet coke was easily pul-erised, and, when mixed with a suitable binder, would nake an excellent fuel briquette adapted for domestic se. This fuel could be burned in a house furnace in-tead of anthracite, and could be distributed for one-alf the cost of anthracite. — Gas Journal.

OXYGEN-OIL EXPLOSIONS

The second of a series of papers presenting the re-ults of an investigation being made by the United States Bureau of Mines, on oxygen-oil explosions, deals with the spontaneous ignition of metals in oxygen nder pressure. The experiments described in this paper were undertaken to determine (1) the relation-ship between oxygen pressure and the ignition tem-perature of the metals most frequently used in high-pressure oxygen apparatus and (2) the metals most suitable, as regards safety and freedom from combus-tion, for use in high-pressure oxygen systems. A study was made of the relation between ignition tem-perature and pressure for iron, copper, and brass, which are the three materials usually employed, and for lead.

It was found that, under high oxygen pressures, iron and steel burn very readily and completely, and if once ignited propagate a flame with almost explo-sive velocity. On the other hand, brass and copper appear to burn only very slightly. With brass, a slight combustion apparently takes place.

It would seem that the use of iron or steel in the construction of manifolds, etc., might be a dangerous practice once the material is raised to its ignition tem-perature. It seems probable that copper, and per-haps brass, would survive a higher temperature than steel, and, at most, should any condition cause the manifold and piping to reach a temperature sufficiently high to melt the metal, it would merely melt away and release the oxygen, without burning or propagating a flame.

The lowering of ignition temperature with increase in oxygen pressure is shown graphically and, so far as known, has not previously been demonstrated in any published experiments. The greatest change noted is in iron. At atmospheric pressure, iron in oxygen ignites at approximately 930 deg. C., while at 2,000 pounds per square inch the ignition temperature drops to approximately 600 deg. C.

The results of these experiments are given in Serial 2521, by J. J. Jakowsky, assistant engineer, and E. W. Butzler, assistant to physicist. A general outline of the problem of oxygen-oil explosions being studied has been given in the first report, Serial 2507. Copies of either or both reports may be obtained from the Department of the Interior, Bureau of Mines, Wash-ington, D.C.

GRATES AND FURNACES FOR LIGNITE CHAR

Grates suitable for burning lignite char in an or-dinary cook stove have been designed by the United States Bureau of Mines, and tests run in the labor-atory at Pittsburgh proved that they will burn this fuel successfully. In order to prove that this fuel is practical in the preparation of meals, this range, equip-ped with special grates, and a cooking stove of Ger-man origin, were installed at the domestic science school of the Carnegie Institute of Technology, where they were actually used for cooking. Later the Ger-man stove was removed to the residence of a Bureau of Mines employee, where a test of lignite char under actual household conditions was made. In both cases the lignite char proved an admirable fuel, and was said to be second only to gas in its convenience and prac-ticability.

A practicable heating stove of the base burner type was also developed, with a special magazine feed, cone grate, and a shaking grate for ash removal.

Further work will be required to develop a grate which may be considered entirely satisfactory for burning lignite char under heating boilers. The chief difficulty is in the riddance of ash and clinkers at higher ratings.

AIR-SWEPT TUBE MILLS

Ball and tube mills have become the most important machines of the day for fine crushing. Their maximum capacity is not developed ordinarily, however, because of the prevalent practice of allowing finely ground material to remain in the mill, along with coarse particles, where it impedes the crushing action of the balls or pebbles. Numerous expedients have been developed, in both wet and dry grinding, with a view to overcoming this difficulty, and in some cases a distinct improvement in both capacity and cost has resulted.

The Kennedy Air-Swept Tube Mill, made by the Kennedy-Van Saur Mfg. & Eng. Corporation, 50 Church St., New York, has demonstrated conclusively the economy of removing the crushed material as soon as it has reached the required degree of fineness. For a number of years they have experimented with the principle, and for the last two years have had their new mill in operation in commercial plants, where they have tried it out on various kinds of material with highly satisfactory results.

The photograph herewith shows a plant used for pulverizing limestone for agricultural and other purposes. The 6 ft. by 12 ft. Air-Swept mill produces 11.8 tons per hour of which 84.5 per cent. passes through 200 mesh, 94.8 per cent. through 150 mesh, and 99.2 per cent. through 100 mesh. A draft is induced through the mill by a 60-inch fan which lifts out the smaller particles as soon as they are formed. The speed of this fan can be regulated to give whatever degree of fineness is required. The dust is separated in cyclones, of which three, of 7-foot, 10-foot and 4-foot sizes, are used in the above plant. All the dust from the 10-foot cyclone passes through a 350-mesh screen.

The motor required for this mill is of 125 H.P., and for the fan, 12 H.P. In operation the mill consumes less than 11 H.P. per ton per hour, in producing the material noted, while the ordinary mill requires 25 H.P. or over when making a coarser material.

In addition to its use in the manufacture of cement, in various chemical plants and in pulverizing coal, this principle of air separation is already finding a general use in the grinding of feldspar and flint for the ceramic industries. In this case, of course, flint pebbles must be used instead of steel balls. It seems possible that it might be used to advantage in the separation of asbestos fibre from the enclosing rock, as the fibre would be removed as soon as released and thus subjected to a minimum of the destructive cutting action.

PREPARATION OF SUPER-REFRACTORIES

Experimental work in the development of refractories from artificial sillimanite designed to be superior to the natural refractories now in use is in progress at the Northwest Experiment Station of the United States Bureau of Mines, Department of the Interior, at Seattle, Wash. The work is being done in co-operation with ceramic trade interests. Sillimanite is the normal silicate of alumina, containing 63 per cent. Al_2O_3 and 37 per cent SiO_2, and is also made artificially in the electric furnace. The best compound found is one a little richer in alumina than the pure sillimanite. One of the principal problems is the presence of impurities in the local clays that affect the fusing point. It was found that iron oxide present as impurity could be partly removed by reduction, but magnesia and lime could not be removed.

CHROMIUM

The only important ore of chromium is chromite or chrome iron ore. It is found in peridotite and in serpentine derived from peridotite. It occurs in irregular bunches, in vein-like masses, often mixed with magnetite. The discovery of masses of black, hard, heavy metallic mineral in serpentine or peridotite is not necessarily a find of chrome iron ore; it may be magnetite. On the other hand, chromite that is mixed with a little magnetite might be mistaken for magnetite.

Plant used for pulverizing limestone, consisting of a tower drier, disc feeder, air swept tube mills, cyclone separaters and bins. The product is 99.2% through 100 mesh, 94.8% through 150 mesh, and 84.5% through 200 mesh. Capacity, 11.8 tons per hour, and 137 H. P. required.

THE MINING DISTRICTS

By THE JOURNAL'S CORRESPONDENTS

NORTHERN ONTARIO

Porcupine. — The quarterly report of the McIntyre or the three months ending September 30th, shows a ubstantial increase in earnings. The gross recovery mounted to $681,000 and costs were $407,500, leaving operating profits of $273,500. Non-operating revenue was $19,500, and total profits, before taxes and depreciation, $293,000. Taxes for the period were $15,500, leaving net profits, before depreciation, of $277,500. For the fiscal year ending June 30th gross recovery was at the rate of $562,000 a quarter, and net earnings, before plant depreciation, $230,000 a quarter. It is rumored that negotiations are under way for the disposal of the balance of the McIntyre treasury shares to English interests. At the annual meeting it was intimated that in the comparatively near future the company might be faced with large expenditures to sink a new shaft to a depth of approximately 5,000 feet, and that funds for this purpose would have to be obtained by building up the surplus, thus deferring increased dividends, or by raising money by the sale of securities. If a deal were made for the stock in England, current earnings would be sufficient to justify increased dividends.

With the dividend cheques of $1.00 a share sent to shareholders, directors of the Dome advise that after November 14th share certificates should be sent to the Empire Trust Company, New York, in order to have them exchanged for new shares, on the basis of two new shares for each one of the old. The directors have no intention of making any further split-up at present.

Officials of the Porcupine Grande report that diamond-drilling has shown two ore-bodies, lying comparatively close together, and located in an area north of the underground workings. One body is stated to assay $11.00 over a width of 10 feet, and the other $44.00 across 7½ feet. The property is being developed by the Ontario National Development Company.

The West Dome Lake has cut its No. 2 vein, at a depth of 700 feet, where it shows a width of approximately 3 feet. The shaft will be continued to 1,000 feet, and a station will be opened at 750 feet.

The annual report of the Goldale Mines, which has been mailed to shareholders, holds out considerable encouragement for the future. At the annual meeting shareholders will be asked to ratify a by-law authorizing the directors to sell, option, lease or otherwise dispose of any of the Company's property. This is believed to be in connection with the proposed amalgamation of the Goldale, Plenaurum and Armstrong-Booth properties. Messrs. B. H. Westlake and F. M. Loper, Directors of the Kerr Lake Company, were elected to the Goldale Board.

The Premier Paymaster shaft has reached 600 feet, where a station is being cut, but sinking will be continued immediately to the 1,000-foot level. The property is being actively developed, and in addition to underground work, several diamond-drills are being used.

Kirkland. — During the month of September the Teck-Hughes Mine produced bullion of a value of $108,679, which constitutes a new record monthly output in the history of the Company. The mill treated 3,222 tons, having an average grade of $33.73 a ton. Development work is being done on five levels, and results are understood to be quite satisfactory.

The Wright-Hargreaves has recently been developing a new ore-body on the 550-foot level west of the main fault. The ore-shoot has been proven for a length of 300 feet, where it shows values of approximately $9.00 across a maximum width of 40 feet. This ore-body is particularly important, as it is the first commercial ore which has been found west of the fault, and an effort will now be made to open up the same ore-body on other levels.

The Sylvanite has encountered its best ore to date at the new 750-foot level, where a crosscut was run a short distance from the shaft. The shaft sinking is being continued to 875 feet, at which point it is understood that considerable development work will be undertaken.

Sinking has been continued on the Continental shaft, which was put down to a depth of 150 feet by hand. A complete new plant has been installed, and the shaft will be carried to a depth of 600 to 700 feet before any large amount of lateral exploration is undertaken.

The Hunton-Kirkland is crosscutting on the 375-foot level, and while no developments of importance have taken place, conditions are understood to be promising.

BRITISH COLUMBIA

Anyox. — The Granby Consolidated Mining and Smelting Co., in its policy of materially augmenting its ore reserves has been doing much important work this summer on the Outsider Group of mineral claims, Portland Canal. This was taken over from the Brown-Alaska Co., about a year ago and the results of development appear to give much encouragement. Surface and underground exploration has been kept steadily in progress. The plant and equipment available also are being renewed. There is a new dock, and the old ore bunkers have been put in shape to handle 1,000 tons of material a day. A new conveyor is ready to handle ore from the bunkers to the dock and the aerial gravity tram, constructed by the Riblet Tramway Co., of Spokane, is reported to be ready for operation. Electrical power has been provided by the construction of a 1,500-foot pipe line and this is to be supplemented by two Chicago pneumatic semi-Diesel engines. A large bunk house is planned and it is stated that the Company expects to be ready to commence shipments, at least up to 100 tons a day, some time before Christmas. Other properties in the same district are under option to the Company, the whole comprising some 27 mineral claims.

Construction of the building to house the Granby Company's new 1,500-ton concentrator at Anyox is being pushed forward actively as it is the desire to have the plant in operation before the end of the

year. The new plant is being placed on the hillside and is to be housed in a structure of concrete and steel.

Favorable Report on Portland Canal Properties. — B. W. W. McDougall, engineer for H. S. Denny, London, England, who bonded three mineral prospects in the Portland Canal District last July, has spent the summer season surveying the Salmon River zone of mineralization and, while on his way from the north, stated his conviction that the zone is of exceptional width with probability of great richness. On the latter point there was only the Premier Mine as a guide, but it was unreasonable to believe that in a highly mineralized area of such extent there is only one mine. Mr. Denny's properties are the Daly Alaska, the Bush and the Forty-Nine, on which a substantial sum has been spent this year. Mr. McDougall intimated that his report would favor the continuance of development.

"As to the district," Mr. McDougall said, "no one can make a mistake in going ahead. The country, perhaps, is somewhat difficult to operate in, but the geology is right for ore. I have been all the way from Georgia river through the Marmot, Bear and Salmon valleys up to Divide Lake and what impresses me most is the exceptionally wide area of mineralization.

"The Georgia river claims offer the most spectacular showings in the district. There is no place in the camp, or anywhere else in the Province that I know of, where one can get so many croppings that assay several hundred dollars gold to the ton. The fact that the ore is primary speaks well for its depth."

Regarding particular properties, Mr. McDougall mentioned the Dunwell on the Bear River as showing up well and the Fish Creek property as being one of the most advanced on the Salmon river side. The latter has excellent prospects of becoming an early shipper.

He had been through the Premier and, despite occasional reports to the contrary, the mine was holding up magnificently. "They are putting in two new 300 h.p. units of power in connection with the new tunnel being driven about 1,000 feet below the mill. This machinery is to be on the ground by the first of the new year."

Oil Stampede Well Regulated. — Dr. M. Y. Williams, of the department of geology in the University of British Columbia, recently delivered a lecture in the City of Vancouver on "Some Geological Discoveries in the North". After dwelling in detail on the early explorations in the Peace River territory and in the district lying along the northeastern border of British Columbia, he spoke of the finding of oil in that country by the Imperial Oil Co. Dr. Williams commended the enterprise of the Company in working so far ahead of the requirements of the oil industry. Oil had been proved in large quantities and could be developed when it became necessary. He congratulated the Federal Government on the plans that had been made to handle the threatened oil rush of the year 1921. Plans had been prepared for the erection of government offices for the recording of claims and strict regulations were made to prevent men lacking the required physical hardihood and knowledge from undertaking the journey. The result was that only men picked by the Royal Northwest Mounted Police were permitted to start and the tragedies which in the past almost invariably have accompanied stampedes to distant and little known districts were thus avoided.

Enlarged Hydro-Electric Plant. — The West Kootenay Power & Light Co., which furnishes power and light to the plant of the Consolidated Mining and Smelting Co., and which supplies most of the other industries of the east and southern parts of the Province, as well as towns and larger communities with their electrical needs, is enlarging its plant at Bonnington Falls, near Nelson. The productive capacity of the plant is practically being doubled.

Kaslo. — A satisfactory understanding having been reached with stockholders, Col. H. H. Armstead is speeding up work at the Utica Mine near Kaslo. The mining plant is being put in shape for a winter of uninterrupted development. It is said that the acquisition of other properties adjoining the Utica is contemplated and that Col. Armstead hopes to build up the largest mining enterprise of the Slocan.

Prospect Sold. — The Maple Leaf Mine, Franklin Camp, Boundary district, was sold at private sale recently to Thomas Dunlap, of Chesaw, Wn., for $4,000. The Maple Leaf Co. made an assignment some weeks ago to Dennis St. Dennis, of Nelson. It is stated that the mine has been developed to the shipping stage and is considered one of the promising prospects of the camp.

Trail Ore Receipts. — Ore receipts at the Trail Smelter, Consolidated Mining & Smelting Co., of Canada, for the first week of October totalled 4,496 tons. The detailed shipments follow:

	Tons
Alamo, Alamo	99
Company Mines	3,635
Cork Province, Zwicky	95
Galena Farm, Silverton	41
Knob Hill, Republic Wn.	152
Quilp, Republic Wn.	108
Rambler, Rambler	8
Silverton, Sandon	283
T. H. Pidduck, Alice Arm	36
Washington, Rambler	39
	4,496

NOVA SCOTIA

Advantages of Merger. — It is little more than three years since all the large coal fields of Nova Scotia were linked up together under the British Empire Steel Corporation. The Sydney district was then the largest producer, just as it is now. But the collieries of this district were much hampered in their development, and the outputs were kept down by boundary disputes between the two largest coal companies of Nova Scotia. Frequent attempts had been made by the heads of governments and others interested to settle the matter without success. It was, therefore, with great acclaim that the general public and the towns most affected hailed the news of the amalgamation which was to set aside the quarrel between the rival companies. Coal outputs had begun to decrease and the combined daily output of these two large companies only amounted to about 12,000 tons a day. It is only fair to state, however, that the war played quite a factor in helping to restrict the output, although the boundary question, gave very serious trouble.

Daily Production Climbing

The Corporation once organized, changes were made in the colliery management. District Superintendent

A. S. MacNeil was transferred from Sydney Mines to become General Superintendent at Glace Bay, over all the Cape Breton collieries. He took with him as his assistant, D. H. McLean, manager of one of the oldest collieries in Nova Scotia, and possibly in Canada. Manager J. R. McNeil was promoted to the position of District Superintendent at Sydney Mines and a number of other changes were made. The wisdom of bringing the two large companies together, under an able staff, began to be felt at once, but is more clearly seen today, when we are in a position to compare outputs. The Sydney Mines daily outputs rose from a little over 2,000 tons to 3,400 tons, and the Glace Bay collieries increased from 10,000 to almost 17,000 tons. This has been all accomplished in the short period of three years. Taking into consideration the fact that the development of nearly all collieries barely kept pace with mine production during the war, and that very little machinery could be brought in, the progress that has been made is very marked indeed. Probably the labor troubles that came as an aftermath of the war affected the outputs more than anything else. But to add more than 50 per cent. to the coal output in three years, in the face of these troubles during which time three collieries were closed down and only one opened up, required men of high intelligence, trained minds, great driving force and untiring industry. It has been accomplished, however, and no matter how we look at it, the work done stands to the credit of all who had part in it. The different superintendents, namely A. McDonald, J. J. McNeil, and P. T. Prendergast, are all men of large experience, good practical mining men and keen students of their profession who are eager to learn and who have the power of application.

New Collieries to Raise Output

One large colliery has stood idle for over two years on the advice of a British mining engineer brought over to advise on submarine areas. Another big colliery will be ready to take its place among the producers early in the coming year. But the work of these two collieries, when in operation, will be partly offset by the reduced production of some of the older collieries. All things considered, the Nova Scotia collieries are in line to give largely increased outputs.

Record of 1923 Will Be Reached Before 1926

Looking back to the year 1913, when a maximum daily output of 20,000 tons were obtained, it will be remembered that Mr. F. W. Gray made a statement that the output would not again reach that amount for many years. This has been verified; but we are again on the verge of halcyon days, and if the outputs increase during the next three years in proportion to the three years just passed, we shall again be reading of new high records. There is little doubt that the 20,000-ton mark will be passed long before the end of 1926.

NOVA SCOTIA COAL PRODUCTION

Coal production from mines of the Dominion Coal Company this year will show quite a substantial increase over 1922 and to the end of September, the output is within a month's tonnage of what it was for the whole of last year. For the year 1922 the total production was 2,845,000 tons, and for the nine months' period of this year the output was 2,527,000 tons. The total shipments for 1922 were 2,400,000 tons, and for the nine months of the present year were 2,340,000 tons.

ALBERTA

Conciliation Board's Decision at Drumheller. — A decision has been given by a Conciliation Board, appointed by the Federal Minister of Labor to arbitrate disputes between employers and employees in the coal field of Drumheller, Province of Alberta, which is of importance, not by reason of the case immediately at issue, but because of the fundamental principle involved, viz., the right of the employer to hire and dismiss for cause that appeals to him as good and sufficient without being compelled to suffer outside coercion.

"The matter in dispute arose from the refusal of the Hy-Grade mine to give employment to James Conroy, the former claiming that under the agreement with the miners, the mine owners had the management of the mine, and the right to hire and discharge the workers in the mine; James Conroy claiming that under the agreement he was entitled to a preference of employment as he had been employed in the mine previous to its closing down for the summer, and should, when the mine again began operation, be given employment in preference to new men who had not worked previously in the mine.

"It appears from the evidence submitted before me that James Conroy was employed in the Atlas mine in 1919 and 1920; in the Hy-Grade mine during a portion of 1921; and in the Elgin mine for a portion of 1921; all of which mines are situated in the Drumheller district. He also was a member of the board of miners of the United Mine Wokers of America from December 1921 to the 22nd day of September, 1922, when he again took employment with the Hy-Grade mine, where he was employed as a miner till April 3rd, 1923, when the output of the mine for the summer was curtailed, and Conroy, without any fault on his part, was let out and paid off. He is a married man and with his wife and two children resided in Drumheller for some years and he resides there now.

"About the 1st of July, 1923, the mine resumed partial operations and Conroy presented himself at the Hy-grade mine and asked for employment, but was refused work, the mine company taking the position that under the contract with the miners the company had the right to employ whomsoever they thought fit, basing its position on the following clause in the agreement:

> **Management of the mine:** — The right to hire and discharge, the management of the mine and the direction of the working forces are vested exclusively in the company, and the United Mine Workers of America shall not abridge that right.

"Conroy took the position that under the agreement, where the mines closed down or where a miner was laid off without any fault on his part on account of suspension of work, on resumption of work at the mine he should be given preference to new men, and that new men should not be taken on at the mine while the old men who formerly worked at the mine were willing to come back, and he based his position on the following clause in the agreement:

> **Preference of employment:** — In case an employee is thrown out of employment, unless discharged, he shall be given preference over new men in other mines in the same camp operated by the same company.

"The Hy-Grade mining company took the position that this clause in the agreement did not apply to the Hy-Grade mine, as this mine operates only one colliery and only one mine or opening at that colliery; that this clause in the agreement applied only to companies that operated more than one colliery and more than one mine at each colliery; that this applied to mines of the Crow's Nest Coal Company which operated mines at Coal Creek, Michel, and had several mines or openings at each of those places; but that this was not the condition of the Hy-Grade mine.

"The evidence on behalf of Conroy shows that when he learned that new men were employed in the mine he went to Mr. McConkey, the managing director, and asked for employment, when he was told by McConkey that there was no place for him at the mine, and that he did not intend to employ him.

"From the evidence of McConkey and Harry Crowder, mine manager, it appears that Conroy, before the time he applied to the managing director for work and before any new men were taken on at the mine, went to the mine manager, Harry Crowder, and asked for employment and when he was told there was no work for him he became very abusive, calling the mine manager vile names and using obscene language; the manager at the hearing stating that the language used by Conroy at the time was so vile and filthy that he could not repeat it, and that Conroy took off his coat and approached the mine manager in a threatening attitude, saying that he 'would lick him and give the mine all the trouble he could, that he would go the limit unless he was taken back to work.' This disturbance took place in the presence of twelve employees of the mine.

"Neither Conroy nor his representatives at the hearing denied the happening of this episode as described, but claimed that Conroy's attitude towards the mine manager was caused by his hearing that new men were employed in the mine in preference to him, and that he became indignant and threatened the mine manager when the mine manager claimed that no new men were taken on.

"The managing director in his evidence stated that the conduct on the part of Conroy as shown in his menacing and threatening attitude towards the mine manager had a tendency to create discord and trouble among the workers in the mine and to disorganize and disarrange the working therein, that it would be detrimental to the interest of the owners and shareholders of the mine to employ Conroy, who threatened to do bodily harm to the mine manager and damage to the mine property.

"Under the clause of the agreement cited — 'Management of the Mine' — it is clear that the company has the right to hire and discharge and are responsible for the management and working of the mine.

"To my mind the clause cited — 'Preference of Employment' — and relied on by Conroy must be read with the clause 'Management of the Mine', which gives the right to the company to hire and discharge, and this clause is not varied or changed by the subsequent clause 'Preference of Employment,' so as to compel the company to employ someone who would be detrimental to its interests, as the evidence here discloses.

"Under the evidence introduced at the hearing I do not believe that Conroy has made out a case to compel the company to give him employment in the mine and this is my finding."

(Signed) "James Smith, Chairman."

INVESTIGATION OF MINERAL FILLERS

The investigation of the availability of certain minerals for use as fillers, together with a study of their physical and chemical characteristics, and their adaptability to commercial uses, is being continued by the Department of the Interior, through the Bureau of Mines. The South has extensive deposits of clays, ochres, bauxite, talc, graphite, etc., and the purpose of this study is to determine their value for use as fillers in making linoleum, paper and other commercial products.

The laboratory study of the size and character of grains of non-metallic mineral fillers has been completed. The results show that these characteristics have an important bearing on the applicability of a mineral filler and the types of manufactured products in which it can be used.

Laboratory work on Georgia and Alabama white clays to determine their value for filler use has been completed. The samples investigated included 31 Georgia and 11 Alabama clays. Of the Georgia clays, 17 were selected for more extended semi-commercial tests, and 500-pound samples were sent to the Ceramic Experiment Station of the Bureau of Mines at Columbus, Ohio, for washing, pulverizing and dispatching to the manufacturers who are co-operating in the factory tests. The laboratory tests have shown that a number of the Georgia clays tested are equal or superior in quality to the imported foreign clays now largely used in the paper trade. The bureau's tests also indicate the clays are of value in rubber filling, and rubber manufacturers are being furnished with samples of the Georgia clays, to test their value in rubber compounding.

DOLOMITE FOR REFRACTORIES

Research work on the utilization of dolomite in refractories is being continued by the Ceramic Experiment station of the Bureau of Mines, Columbus, Ohio. The main problem being studied is to combine the lime in the dolomite so that it will be non-slaking and at the same time hold up the refractories, thereby rendering available abundant deposits of dolomite for extensive use as a basic refractory. Work previously done by the Bureau of Mines on different fluxes for rendering dolomite refractories non-slaking indicated that by careful selection and preparation, refractory bricks could be made, one of the best fluxes tried being alumina-iron flux. More recent work done by the bureau consisted of slaking time tests on varying proportions of dolomite mixed with an alumina-iron flux. The proportion of flux to dolomite was varied between 5 and 20 per cent. The refractory properties as well as the slaking tendency of these mixes was studied. After the best proportion of flux to ground rock was determined, bricks were made by the soft mud and dry press processes, using both organic and inorganic binders. Then methods of firing to produce sound bricks were studied. As a result, a composition has been found which, when compounded with the proper binder and burned after a given procedure, produces a strong, non-slaking brick of high refractoriness. The

bricks are satisfactory in every respect, except that uniform shrinkage has not been completely attained. During the coming year, bricks will be produced and tried out in the industry.

LOSS OF GASOLINE BY EVAPORATION

The use of cooling systems in vapor-tight tanks should serve as a means of checking evaporation losses of gasoline which amount annually to 3 to 4 per cent of the stocks accumulated during the winter season and whose value runs into millions of dollars, says Serial 2531 of the United States Bureau of Mines, now available to the public.

Hamilton, Ontario
Montreal Winnipeg

PROVINCE OF QUEBEC
MINES BRANCH
Department of Colonization, Mines and Fisheries

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, etc.

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

MINER'S CERTIFICATES. First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. The price of this certificate is $10 and is valid until the first of January following. This certificate gives the right to prospect on public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres.

WORKING CONDITIONS. During the first six months following the staking of the claim, work on it must be performed to the extent of at least twenty-five days of eight hours.

SIX MONTHS AFTER STAKING. At the expiration of six months from the date of the staking, the prospector, to retain his rights, must take out a mining license.

MINING LICENSE. The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cents an acre per year, and a fee of $10.00 on issue. It is valid for one year and is renewable on the same terms, on producing an affidavit that during the year work has been performed to the extent of at least twenty-five days' labour on each forty acres.

MINING CONCESSION. Notwithstanding the above, a mining concession may be acquired at any time at the rate of $5 an acre for SUPERIOR METALS, and $3 an acre for INFERIOR MINERALS.

The attention of prospectors is especially called to the territory in the North-Western part of the Province of Quebec north of the height of land, where important mineralized belts are known to exist.

PROVINCIAL LABORATORY. Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY, 228 ST. DENIS STREET, Montreal, for the determination, assays and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensure results of undoubted integrity and reliability.

The bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of the Province, on application addressed to

HONORABLE J. E. PERRAULT,
MINISTER OF COLONIZATION, MINES AND FISHERIES, QUEBEC

BRITISH COLUMBIA
The Mineral Province of Western Canada

Has produced Minerals valued as follows, Placer Gold, $76,542,203; Lode Gold, $109,647,661; Silver, $59,814,266; Lead, $51,810,891; Copper, $170,723,242; Zinc, $24,625,839; Coal and Coke, $238,289,565; Building Stone, Brick Cement, etc., $36,605,942; Miscellaneous Minerals, $1,358,839; Making its mineral production to the end of 1922 show an

Aggregate Value of $734,259,619

The substantial progress of the Mining Industry of this Province is strikingly exhibited in the following figures, which show the value of production for successive five-year periods: For all years to 1895, inclusive $94,547,241; for five years, 1896-1900, $57,605,967; for five years, 1901-1905, $96,509,968; for five years, 1906-1910, $125,534,474; for five years, 1911-1915, $142,072,603; for 5 years 1915-1920, $189,922,725; 1921, $28,066,641; for the year 1922, $35,158,843.

Production During last ten years, $339,280,940

Lode-mining has only been in progress for about twenty-five years, and not 20 per cent. of the Province has been even prospected; 300,000 square miles of unexplored mineral bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than those of any other Province in the Dominion, or any Colony in the British Empire.

Mineral locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full information, together with Mining Reports and Maps, may be obtained gratis by addressing

A CRANE PRESSURE REGULATOR WHICH TRANSFORMS HIGHER PRESSURES TO ANY CONSTANT PRESSURE

INCREASING THE UTILITY OF A PLANT

Low pressure steam or air delivery direct from higher pressure mains and constant pressure delivery are possible with Crane pressure regulators. Steam at the correct pressure for small power units or low pressure heating, constant pressure steam for process heating and air for blasts, heaters, and low pressure tools can be taken from higher pressure mains through this automatic valve without loss of one bit of heat or energy. Crane pressure regulators are furnished with unions or flanged connections, for any reasonable capacity and working pressure. Let the Crane representative help you to increase the utility of your distribution piping with this dependable money-saving specialty.

The "Stopehamer" is designed to drill "upholes" from 20° above the horizontal to vertically upward as in raising and stoping. It is the machine that should be used for this type of work.

Mining is carried on much more scientifically now than formerly. Ore is located no longer with guess work prospect shafts but by means of bore holes. The mine is laid out and the mining method and its sequence of operations planned before the shaft is sunk.

The use of make-shift equipment is being discontinued, as each operation is most efficiently and economically done by a machine designed for one special job.

The "Stopehamer" is made in many types and sizes, one of which will exactly suit your rock drilling conditions.

Bulletins on request.

Ontario's Minerals

PROVINCE OF ONTARIO

Hon. CHARLES. McCREA, Minister. DEPARTMENT OF MINES *Thos. W. Gibson*

Mineral Areas

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favourable for the occurrence of minerals 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver veins of Cobalt, Gowganda and South Lorrain occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

Economic Minerals

In addition to the above, practically all economic minerals coal and tin excepted are found in Ontario: — actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluor spar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, Portland cement, brick and tile, meet every demand.

Mineral Production

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1922 to be worth $62,202,169, of which the metallic production was $38,190,711.

The following figures show the growth of Ontario's mineral industry by five year periods since 1891 when a Bureau of Mines was first established.

Year.	Value.	Year.	Value
1891	$4,705,672	1911	$41,976,797
1896	5,235,003	1916	65,303,822
1901	11,831,086	1918 (Maximum war output)	80,308,972
1906	22,388,383	1921	48,128,387

Dividends and bonuses paid to the end of 1922 amounted to $28,096,699 for gold mining companies, and $86,238,185 for silver mining companies or a total of $114,334,884

Mining Regulations

A miner's license costs $5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of $2.50 or $3.00 per acre, depending on location in unsurveyed or surveyed territory.

Assay Office

The Provincial Assays Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

Publications

Hercules Pine Oil Saves You Money

Experienced flotation operators are finding pine oil the most economical reagant they can use. It is the best frother known and recovers more concentrate than any other. It is the cheapest flotation oil when compared with others on the basis of the net cost per ton of ore treated.

Hercules Pine Oils are steam-distilled and consequently superior to oils distilled by other methods. They are produced under strict chemical control and are made to conform rigidly to specifications that will meet your requirements. A comparison of samples will prove their superiority.

Write for booklet No. 200 which gives specifications for our standard grades.

Adding Impetus To The Development of Mining

The development of Canada's enormous natural resources will affect her whole future. Her vast mineral wealth, as yet practically untouched, is to-day attracting world-wide interest from far-seeing investors.

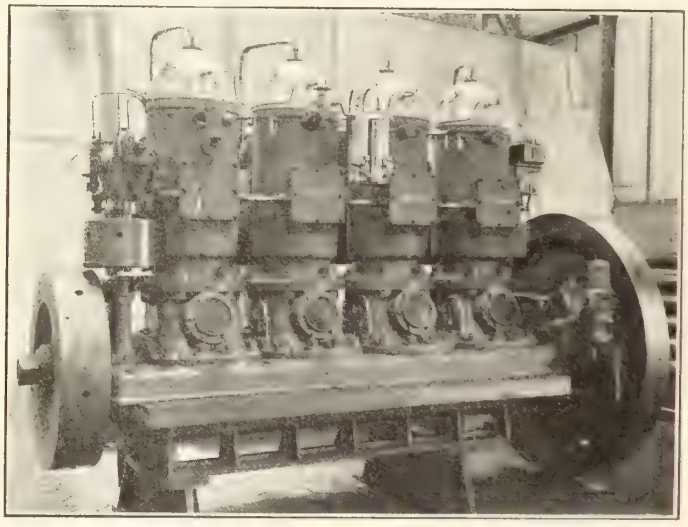
It is appropriate that the Imperial Bank, whose policy has ever been to concentrate exclusively on Canadian affairs, should be powerfully furthering that interest. This Bank, by placing branches at strategic points throughout the mining districts, has materially aided the whole industry.

Those who contemplate becoming connected in any capacity with mining would be well advised to take advantage of this Bank's facilities.

IMPERIAL BANK OF CANADA

Peleg Howland, President. A. E. Phipps, General Manager.

Holland has over 10,000 semi-Diesel engines in service



KROMHOUT Semi-Diesel Engine 200 B.H.P.

For small powers, say up to 500 B.H.P. we recommend the SEMI-DIESEL in preference to the DIESEL engine :

BECAUSE :

Cost is less---therefore Capital and interest charges less.

It has fewer working parts, operates at a lower Pressure.---therefore depreciation and cost of upkeep less.

Is lighter and less bulky---therefore easier to transport and install.

Is of more simple design---therefore obviates the services of a skilled engineer.

Particularly suitable for standby or Reserve Power.

THE EMPIRE COUNCIL OF MINING AND METALLURGICAL SOCIETIES

Ir. Hugh F. Marriott, past President of the Insti- on of Mining and Metallurgy, was entertained at ner by the British Columbia Division of the Cana- n Institute in Vancouver on Oct. 29th., and thus imenced a tour of Canada upon his important mis- n under the most auspicious conditions.

Ir. Marriott is touring the Empire as the official resentative of the Institution of Mining and Me- urgy and the Institute of Mining Engineers to can- s opinion of a project that is of vital moment to engineering professions.

Much has been written of late of the increasing need scientific methods in all branches of mining and tallurgical work, and it has been conceded that the ue of technical training and experience can hardly overestimated. Greater and greater demands are de upon the engineer, who is expected to absorb, intensive study and devotion to his life work, the ts and theories upon which to form judgments that ll be of value to others; but what has been done to sure to the engineer the justly-earned fruits of his rifice and training? So far nothing has been done. cieties are formed through the medium of which he y still further exploit his knowledge. By means of ir transactions he can make public his discoveries, d can derive such satisfaction as is to be found in sociation with his fellows.

Although attempts have been made, and in some ses have served to a limited extent to give protec- n to the members of a Society in such manner as is ustrated by the Law Societies of the legal profes- n, it has been increasingly manifest that the indi- dual engineer is, in the main, left unaided in the ndication of his position and in determining the size his fee or salary; and from the very nature of his lling, he suffers a serious disadvantage thereby.

A very real difficulty in the establishment of any ntral organization to cope with this situation is the verse nature of the mining engineer's practice and ie ramifications of the profession as a whole. The rofession at its beginning years ago may be likened a young tree supporting its tender shoots. From at we have arrived at a stage where the fully de- loped branches form an important and integral part f the whole, and dominate it's very character. It ould be obviously an act of unwisdom to attempt to npose restrictions, standards or penalties upon the eedom of such branches' natural growth.

In the proposal that Mr. Marriott is submitting to the members of the profession throughout the Empire, this difficulty has been overcome, and a plan is outlined by which, while preserving absolute freedom of action to sister Societies, a coöperative means is provided for preserving the integrity and strengthening the influence of the mining and metallurgical professions. Briefly, the plan is to form an Empire Council of Mining and Metallurgical Societies composed of representatives from all the established organizations throughout the British Empire, which shall be empowered to establish a Register of Engineers according to such high standards of repute and efficiency as it may deem to be expedient. According to this proposal, it is not incumbent upon the affiliated societies to modify their own regulations or standards in conformity with the requirements of the Register; but on the other hand, it is conceivable that the influence of such societies may be greatly enhanced by their participation in the activities of a united profession thus stabilized in the eyes of the world. , ,

We accord our heartiest support to this movement and note with satisfaction that a resolution in favor of it was passed unanimously by the Vancouver members of the British Columbia divison of the Canadian Institute of Mining and Metallurgy, at this, Mr. Marriott's first meeting in Canada.

Mr. Marriott was able to tell his audience that the suggestion had been accepted with enthusiasm in Australia, and we trust and believe that no less cordial a reception awaits him in this country. We may add, in assurance of our appreciation of the personal effort entailed, that his world-wide tour upon this mission to engineers is of itself an inspiration.

MORE TECHNICAL OFFICERS FOR QUEBEC BUREAU OF MINES

Hon. J. E. Perrault has authorized the appointment to the technical staff of the Bureau of Mines at Quebec of two mines inspectors and one or more mining geologists. He has thus acted promptly in fulfilling the promises recently made that the mining industry in his province would receive more adequate consideration from the Government of which he is a member.

One mines inspector has been appointed already, and is on duty at Thetford Mines. He is Mr. Eugene Larochelle, who graduated from the Ecole Polytechnique of the University of Montreal in 1916 with degrees in civil and mining engineering. Since graduation he has been employed at the Bell Asbestos Mines, where

he had charge recently of all the engineering work. Mr. Larochelle entered upon his new duties on October 15th. In addition to the inspection of the asbestos mines from the standpoint of the safety of workmen, he will act as assessor for the collection of the royalty on asbestos.

For years past Mr. T. C. Denis, Superintendent of Mines at Quebec, has said both publicly and privately that a gold boom in the province would result in the rehabilitation of his long neglected Bureau. He has proved to be a true prophet; and we are sure that from now on the Quebec Bureau of Mines and the province's mining industry will receive from the political administrators of the province the attention and the consideration that are its due.

HOLLINGER RESEARCH FELLOWSHIP

During the last two years a scientific research has been in progress in the laboratories of the department of mining engineering of the University of Toronto with a view to determining the essential qualities of various crushing mechanisms, particularly of ball mills. Some of the results have been published in a series of papers by H. E. T. Haultain and F. C. Dyer, a striking feature being the "movie" pictures showing the action and paths of the balls in ball mills. The design and construction of the special apparatus required for these researches has involved a considerable expenditure of money. The Ontario Department of Mines and the Advisory Research Council have contributed to the good cause funds that have enabled the researches to make the special tube mill apparatus and to buy the requisite "movie" camera, and to build a special set of rolls and an integrating dynamometer wherewith to attack another phase of the crushing problem.

This research work is expensive, and not the least expense is the "keep" of the researcher—though few researchers ask for more than a decent living. Hollinger Gold Mines, Limited, have come to the rescue. They have presented to the University a fellowship amounting to $1,200, which is to be given to the Hollinger Research Fellow for nine months' work on the problem of crushing. The fellowship has been awarded to Mr. H. F. Farncomb, B.A.Sc., of Trenton, Ont.

The management of Hollinger have spent a good deal of time and money on an investigation of the crushing problem during the last year or two by comparing the efficiencies of the various mechanisms available. This work has, no doubt, brought home to them as never before the meagre basis of fact upon which our ideas about crushing are based, and the crying need for an understanding of the principles involved. A fortunate outcome of the research they have now subsidised will return the investment many fold, not only to themselves but to the whole world of mining men. In the hands of Professor Haultain and his able staff it is bound to be a good investment. Hollinger's example might well be followed by othe of our wealthy mining corporations. The history research in our universities shows a manifold retu for the comparatively small sums expended by the

THE QUALITY OF PUBLICITY

The hearty reception accorded to Mr. C. M. Cam bell at the Trail meeting of the Institute when he rea his paper on "Publicity in the Mining Industry" si nified more than a mere appreciation of his coura in advocating the cause of unwelcome truth. The me ing admitted the truth, and several members expres ed their opinion of the need for a broader understan ing of how the mining industry can best state its ca to the public. Stripped of all personalities, the di cussion that has engaged the attention and interest the members of the Institute for some months past r solves itself into a consideration of the merits of tw points of view, both of which should be deemed as fa removed from the domain of philosophical reflectio as they are beyond the scope of the meticulous stat tician.

The extremes of these divergent points of view u hold the free and unrestricted use of inductive an deductive powers in the outlining of possibilities the one hand, and the ultimate dominance of col facts on the other hand. The application of thes points of view to the problem of publicity in mine matters brings one face to face with two oppos interests that in the very nature of commercial rela tions must be always, in their essentials, as separat as the poles, — the interests of vendor and purchase To coördinate these interests is one of the minin engineer's chief functions. A man who is led by a unbridled imagination does not deserve to be call an engineer, any more than does a man who devot himself solely to academic facts and yard-stic definitions.

The Institute represents the mining engineering pr fession in Canada, and it is therefore appropriat that the trend of publicity, as it affects the relatio between people with properties to sell and those wit money to invest, should be scrutinized closely by its members.

Some may be of the opinion that it had been bette not to raise this issue publicly. We are not of tha school. We welcome the opportunity to say that our mining industry requires the assistance neither of the visionary nor of the disinterested gentleman who sell near-mines on commission. The ideal of the mining engineer will always be to formulate his conclusions with due regard to known facts, and at the same time to include as much of the future as sound judgment and a well-rounded experience will allow. To stat determinable facts does not exhaust the prerogative of the mining engineer; to make himself fully useful he must use these facts to build up in his mind's eye a sane and logical picture of the future. We hold to

e middle way that will neither wreck mining pro-
cts and dissipate capital because of blind confidence
the future, nor will discourage investment and
ock progress because of a lack of vision.

RICE-CUTTING IN WINNIPEG COAL CONTRACTS

The Winnipeg School Board recently awarded the ntract for 9,000 tons of bituminous coal to a local ealer who supplied Pocahontas coal for $9.70 per n, in competition with Alberta coal, which could t be sold profitably in Winnipeg at that price. In e October issue of *Western Canada Coal Review*, r. Geo. R. Pratt, Fuel Engineer to the Government Alberta, discusses this award, and shows that the merican producer who provided this coal is doing at a loss, with a view to holding the Winnipeg arket against the smaller and financially weaker mine perators in Canada.

Mr. Pratt states that the cost of this coal, delivered Winnipeg, is $9.98 per ton; therefore it is being sold a loss. However, the American organization that trying to hold the Winnipeg market is very large. nd to it this temporary loss is the merest trifle.

The School Board of Winnipeg have got some heap coal this year. There is no assurance that this w price will be continued; in fact it is certain that will not be continued. This instance illustrates the ell-known means whereby a large and financially trong company eliminates the competition of a maller rival by a temporary price-cutting campaign. t is doubtful if, in the long run, the customer reaps permanent advantage from the temporary lowering f prices; the successful competitor is sure to make im pay up for the losses incurred.

When the price-cutting involves international trade nother factor is introduced; a part of our national mmercial independence is at stake. In this case the bject of the American coal company is clearly to oosen the hold of the miners of Alberta on the Win-ipeg market. We were warned at the Institute meet-ngs in Montreal last spring by a representative of the American producers that they would lower their prices n order to retain their Canadian markets. Can we Canadians afford to let the "coal barons" of the United States play with the markets in this country? Most we sit back and see the coal operators of Alberta excluded from contracts because their rivals are pre-pared to sell coal for a time at a loss? Is the effort to provide to the utmost Canadian coal for Canadians to be thwarted by the scheme of an American corpora-tion? Mr. Pratt says "no," and many Canadians will agree with him. The long-sighted view is that the market for Alberta coal must be extended to the economical limit, and no juggling with prices should be allowed to interfere with this natural expansion.

As there is no law to prevent school boards or any other public body or individual from buying cheap coal, whatever the circumstances, and as there cannot well be any such law, it is clearly a case in which recourse must be had to the pressure of public opinion. We heartily commend Mr. Pratt's efforts on behalf of the Alberta coal operators, and hope he and others interested in Canadian fuels will gain the fullest measure possible of public support.

INSTITUTE BY-LAWS MISINTERPRETED

In the *Engineering and Mining Journal-Press* of October 27th, Mr. T. A. Rickard gives some pungent and well merited criticism of the form of recent by-laws adopted by the Canadian Institute of Mining and Metallurgy. When he discusses the matter and the intent of these by-laws, however, he appears to go astray. On the basis of the prerogative of Council to admit to membership "such other persons as shall be otherwise eligible in the opinion of Council," and to associateship "such other persons as the Council may decide to be eligible through connection with mining affairs." Mr. Rickard argues that the Institute is fated to become "nondescript in character" and heterogeneous in membership.

While we shall not attempt to defend the English of the new by-laws, we must point out that Mr. Rickard has misinterpreted completely their import. They are the result of a well-organized movement among Western members of the Institute to effect an object the direct opposite of that stated in the present interpretation. These members believe that the Institute cannot fulfil its principal functions satisfactorily until its members take more seriously the responsibilities of their membership. They have acted vigorously on the basis of this belief, their first move being a revision of the defined status of membership with a view to requiring of new members a higher technical status and to inculcating in old members a more adequate sense of their responsibility to the Institute. The stated intention is to make the Institute more exclusive, rather than to include men on the outskirts of the profession as Mr. Rickard suggests.

On numerous occasions before this by-law was passed we discussed both its merits as a practical measure and the ultimate object its proponents wish to attain. The by-law is now an accomplished fact and so requires no further discussion. The object of those who framed and then worked for the new regulation is entirely worthy and deserves the hearty support of the whole Institute. Our own opinion is that the by-law itself can have comparatively little effect one way or the other on Institute activities. Mere words on the printed page will not count for much; something more vital is required. If the individual members will put their shoulders to the wheel, the Institute will immediately commence to move forward to the position of national influence and importance that is its rightful place.

A Symposium on British Columbia Metallurgy

Descriptions of Plants and Processes at Trail, Anyox and Britannia given at the Trail Meeting of the Institute

By H. G. NICHOLS

The Executive Committee of the British Columbia Division of the Canadian Institute of Mining and Metallurgy has to its credit the assembling of the notable series of papers presented at the Trail meeting last month. It was at Mr. Mortimer-Lamb's suggestion that this opportunity was taken for the simultaneous publication of the facts relating to the mining and metallurgical problems and operations of the three most important technical developments in British Columbia at this time.

The response to this invitation on the part of the Consolidated M. & S. Co. of Canada, the Granby M. S. & P. Co. and the Britannia M. & S. Co. Ltd. exceeded expectations. Particularly in the case of the first named corporation, the symposium prepared by Mr. S. G. Blaylock and his staff, in it's wealth of detail and the frankness with which it discussed problems mastered and methods of treatment adopted, evinced a breadth of view and generosity of purpose that have produced a profound impression in the Province, and has laid, once and for all, the bogey of secret processes in connection with the treatment of complex lead-zinc ore.

The following is a summary of the information laid before the members of the Institute by the officials of the respective corporations.

Trail Practice

The research work of the Consolidated M. & S. Co of Canada, looking to a solution of the problem of treatment, assumed a definite objective with the assurance of a supply of ore of a more or less uniform grade from its Sullivan mine. This ore contains about,

10% lead
12% zinc
32% iron.

Fuming and magnetic separation processes were tried for some time, but were discarded in 1920 in favour of flotation and leaching with the use of the reagents, soda ash, cyanide and copper sulphate, to give selected products. By the addition of cyanide to the crushed ore to the approximate amount of 1/10 lb. cyanide per ton of ore, a differential flotation in favour of the lead mine is produced that gives a concentrate averaging.

65.70% lead
4.5 % zinc
6. % iron

The effect of the cyanide in holding down the zin then neutralized by the addition of copper sulphate, in a subsequent flotation operation a zinc concentrat obtained that averages,

41 % zinc
3.5% lead
17 % iron

The lead concentrate is shipped by rail to the plant Tadanac for treatment first by sintering and roasting the Dwight and Lloyd process, and then by smelting electrolytic rrefining.

The zinc concentrate is treated in the new plant Kimberley, which occupies a floor area of 73,500 squ feet, is 600 feet long and has a total installed po plant of 4,000 H. P. for all purposes outside of crush The crushing plant runs for 8 hours only, 355 H. P. ing installed for coarse, and 390 H. P. for fine crush The total capacity of the plant is 3,000 tons of ore d

The Zinc Plant

The process, which was described at length and ill trated by flow sheets and diagrams, may be simply cribed as follows:

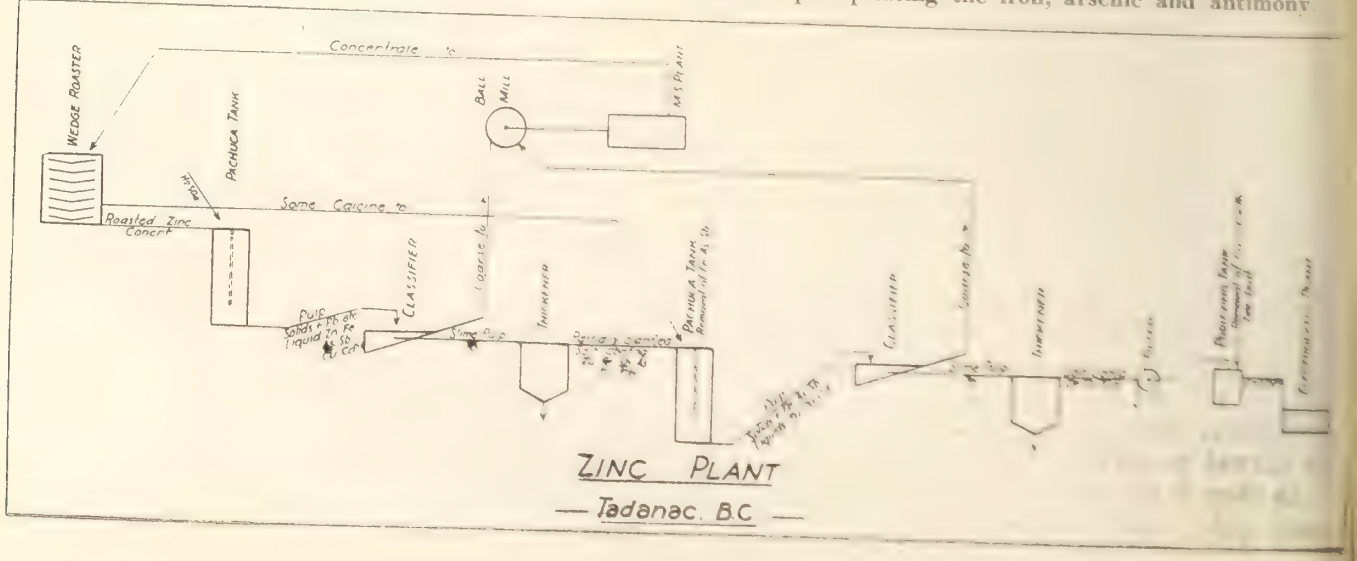
The concentrate is roasted in Wedge furnaces

The calcine is treated with sulphuric acid in Pach tanks.

The mixed pulp is passed through classifiers to remo coarse material. This coarse material is re-ground in b mills, passed through a flotation plant, and the con trate returned to the roaster.

The slime pulp is passed through thickeners for ra separation of solid and liquid.

The solution, containing zinc, iron, antimony, arse copper and cadmium, is passed to a second series Pachuca tanks, where a fresh portion of the calcine f the roaster is added, the zinc oxide in which has the effect of precipitating the iron, arsenic and antimony



The pulp is passed through classifiers and thickeners as in the previous stage, and the solution carrying the zinc, copper and cadmium is clarified in Kelly filters.

The clear solution is treated in purifying tanks with atomized zinc dust; the copper and cadmium are thus precipitated and the pure zinc sulphate solution is passed to the electrolytic plant.

The accompanying diagram represents the process graphically.

The Granby Operations

The principal points of Mr. Clapp's paper on Granby practice were as follows:

The Granby is mining and smelting directly in blast-furnaces about 3,000 tons daily of a massive pyritic copper ore which carries about 2 per cent copper and from 30 to 50c per ton in gold and silver.

Nearly 15 million tons of ore have been developed, in seven ore-bodies. The total value in copper, gold and silver in these ore-bodies is about $75,000,000. There are two types of deposit: First, there are massive pyrite ore-bodies lying at a contact between intrusive greenstone and argillite, which Mr. Clapp describes as having the appearance of tadpoles, with the head pointed upwards against the overhanging argillite roof, and the tail stringing off down the contact and feathering out. The cores of these lenses are normally of higher grade than the outside; an ideal cross-section would show an envelope of silica surrounded by a variously thick band of pyrite, and in the centre, a core of a higher grade mixture of pyrite and chalcopyrite. Second, there are impregnations of chalcopyrite and pyrrhotite along joint planes in the greenstone.

The hypothesis when the property was opened up was that there were approximately equal quantites of these two classes of ore and that they supplemented one another to the extent that, when mixed with some coke and a little limestone, they would smelt economically. It was found, however, that there was not enough free silica in the ore, and as depth was attained, this very necessary constituent gradually disappeared from the greenstone ore-bodies of the second class. To make matters worse, the inclusion of a considerable amount of dyke rock with the ore became unavoidable, more limestone and silica had to be added to the furnace charge, and then the pro portion of the greenstone ore-bodies had to be cut down. This threatened a position where many million tons of ore in these economically unsmeltable bodies would be left, after the pyritic bodies had been exhausted.

A typical analysis of this greenstone ore is as follows:

Insoluble	42.25%
Silica	35
Iron	24
Lime	4
Sulphur	16
Alumina	9
Magnesia	5

New Mill for Flotation Concentrate

Experiments in concentrating this material were begun It was not sufficient to remove the silicate minerals alone, it was necessary to have a concentration that would remove the pyrrhotite as well, and selective flotation was tried. The experiments were successful and a flotation unit of 1,000 tons is now being installed.

A further possibility, indicated by tests made by the Consolidated M. & S. Co., is that the pyrite can also be eliminated by means of differential flotation, and if this proves to be the case, it may be possible to treat the whole output from both classes of ore-body in this way and to discard direct smelting altogether.

The situation that would then be developed is very signficantly expressed in Mr. Clapp's own words. He says: "If there were tonnage enough to justify the installation, and if the subsequent smelting of the concentrates should not prove too expensive, our present system of direct smelting would then be obsolete, and Anyox would become a camp of concentrating mills and reverberatory furnaces. Unfortunately, the problem is not so simple. Our present known tonnage will hardly justify the cost of a reverberatory plant and we have a number of custom ore shippers whose product could not well be handled with the reverberatories. Unless then, we can find some cheap method of smelting flotation concentrates with our present equipment, we must continue to treat at least a portion of our tonnage by pyritic smelting.

Proposed Methods of Smelting Concentrate

"There may be some way in which the flotation concentrate can be handled advantageously in a blast furnace. Several methods have been suggested and are under consideration.

"The first, that of mixing the concentrate with the flue dust and sintering it on the Dwight and Lloyd machine, is simple but expensive and would probably entail some sort of Cottrell dust treatment for the sintering plant as well as for the blast-furnaces.

"A second possibility involves blowing the dried concentrate through either the blast furnaces or the converter tuyeres, which is metallurgically sound, but I fear mechanically weak.

"A third proposal involves feeding the concentrates directly into the mouth of the converters in the same manner as siliceous flux is now fed, accepting a certain high dust loss, which would be caught in the dust chamber and by Cottrells. This would presuppose sufficient molten matte coming from the blast furnaces to liquify the flotation concentrates, or the concentrates can be fused in an electric furnace before adding to the converters.

Another scheme, and perhaps the wildest of the lot, has been to mix the concentrate with a certain amount of coal and make coke from the mixture in our regular by-product coke ovens. Results from experimental work on this have been excellent so far as the resulting coke product is concerned. It takes on the consistency of carborundum and stands hard usage excellently. The only difficulty in the scheme so far found is that, to make a proper mixture, it takes almost twice as much coke as concentrate. In other words, if our ore were all reduced to flotation concentrate, we would have to run on a 200 per cent coke ratio.

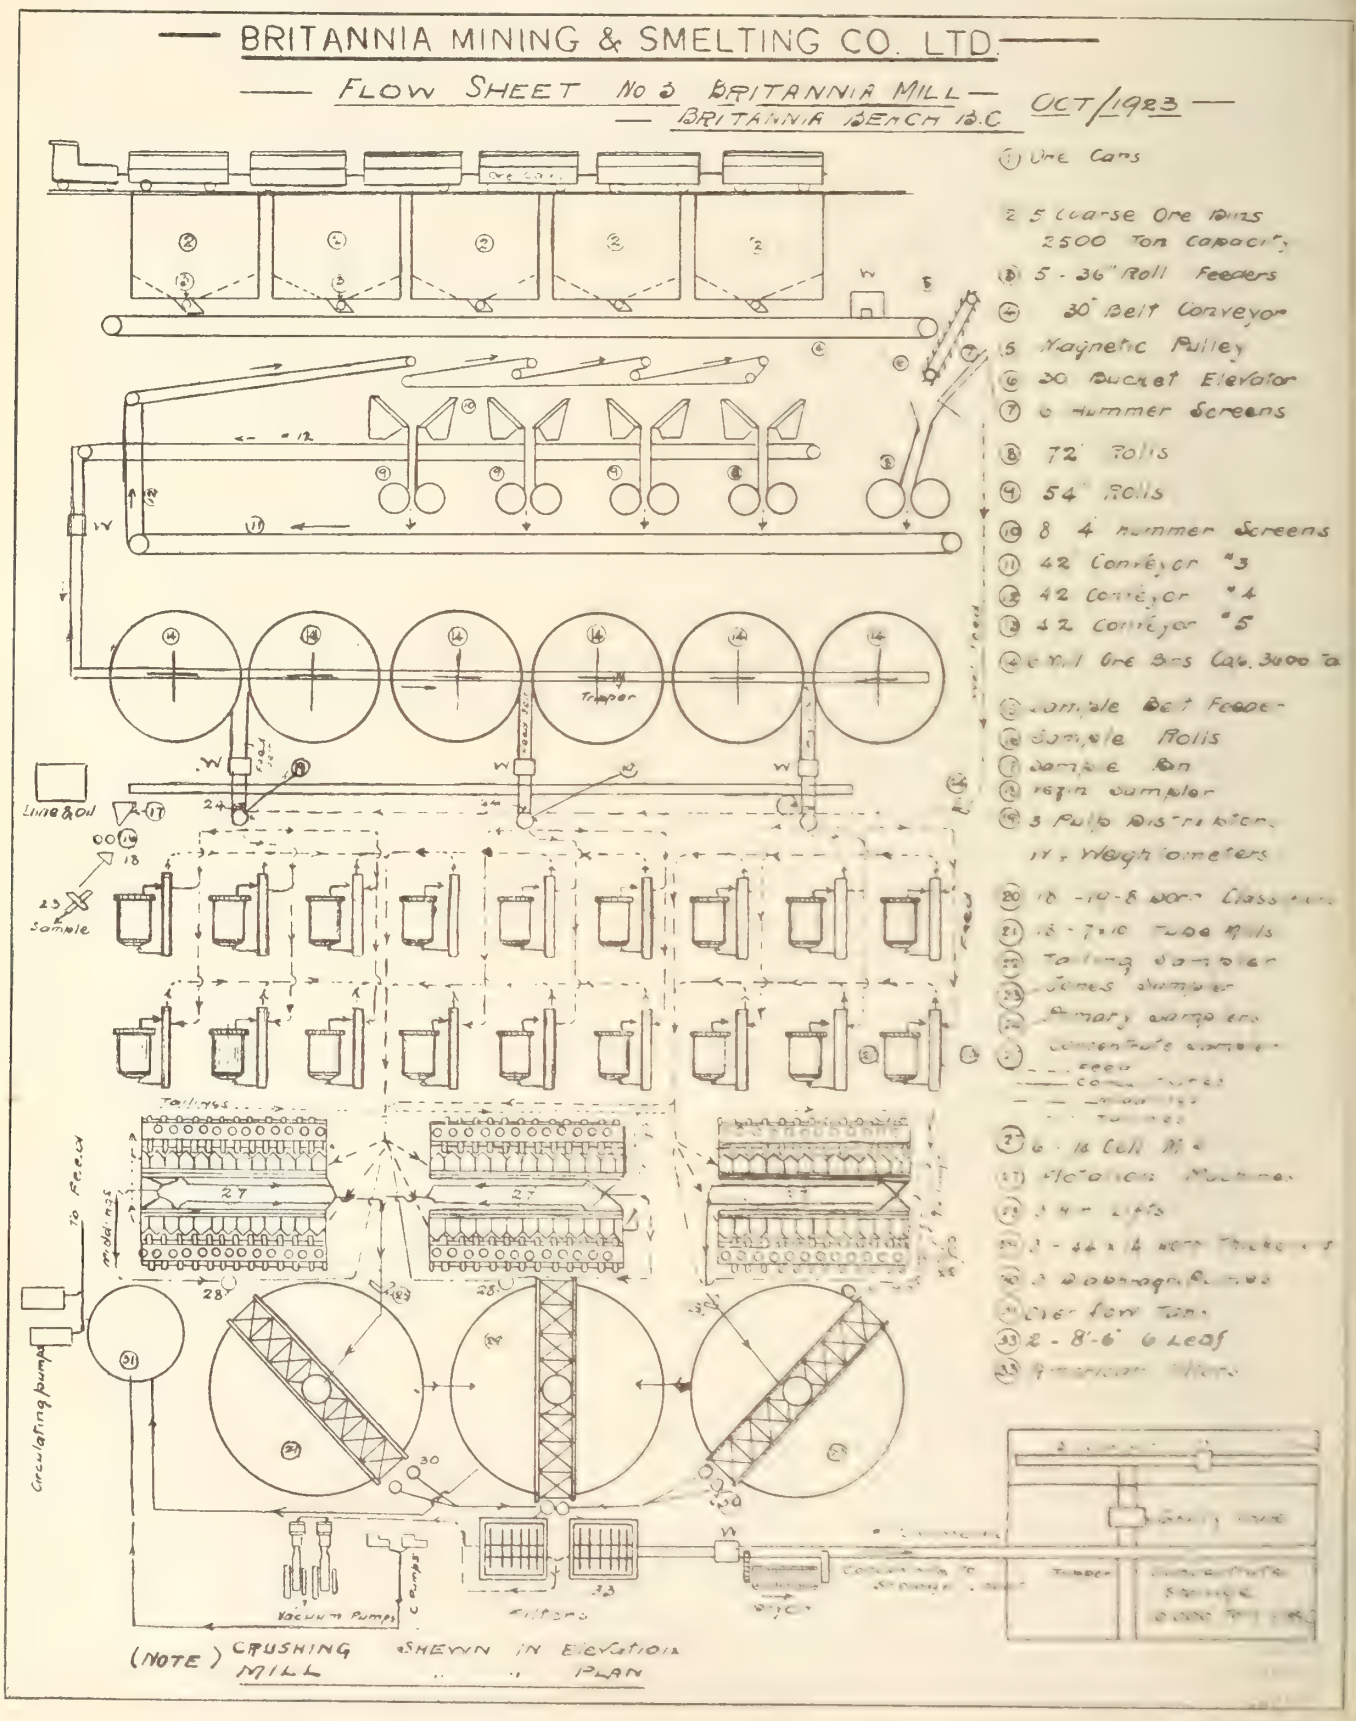
"All these schemes are being investigated, and it may be that a way can be found to handle flotation concentrate in a blast furnace as cheaply and as effectively as low-grade ore. If so, we can then either mine out our ore-bodies at a considerably higher rate of speed or we will have a large amount smelting capacity for custom ores."

The Britannia Treatment

M. A. C. Munro's paper on "Milling Practice at the Britannia Mines" brought out the salient features of this case very clearly. The problems connected with the Britannia ore have always been distinguished from those of the Granby, although the general grade of copper content is practically identical in both cases. The attractions towards direct smelting practice that have been noted in the one case, are entirely lacking in the other. Economic treatment of the Britannia ore has been recognized as being dependent upon efficient concentration. An important factor in this connection is the favourable location on tidewater that allows the reverberatory plant at Tacoma to be used to advantage.

There are distinct characteristics of the Britannia ore that distinguish it from that of the Hidden Creek mines. The ore occurs in schistose, silicified derivatives of quartz and diorite porphyries, in which pyrite and chalcopyrite constitute 17% of the total weight. Due to the almost complete silicification, very little colloidal material results from fine grinding, and the schistose structure promotes greater efficiency in crushing than in the case of the Granby ore, which breaks in large flat pieces.

The whole problem of the Britannia, then, has resolved itself into considerations of economic milling. The first step in the treatment is to provide for dry crushing. The ore contains from 5 to 15% moisture, chiefly contained in the fines which amount to about 20% of the total



weight. The fines are removed by using spraying and hummer screens, the oversize being dried with compressed air and then passed to rolls, tube mills and the Minerals Separation plant. The undersize from the screens is reground and dewatered by passing through Dorr classifiers and tube mills in closed circuit.

Originally, water concentration was employed for partial separation of the coarse mineral, in order to lighten the burden on the flotation plant. Then it was found that a satisfactory recovery could be made by flotation alone, and the use of the Hancock jigs was discontinued. The problem then was to increase the ratio of concentration, which by simple flotation was as low as 6 into 1, and differential flotation was investigated.

93% Recovery by Differential Flotation

The use of both copper sulphate and lime for the purpose of dropping the iron and floating the copper minerals was experimented with, and it was found that copper sulphate gave better results than the lime though it was a more expensive reagent. The trouble with the lime was that while the iron was dropped, the floating of the copper minerals was too sluggish in the normal acid circuit to give sufficiently good extraction. This difficulty has been overcome finally by the use of a small quantity of sodium resinate, and the grade of the concentrate has been more than doubled by means of its use. The iron pyrite can be dropped or recovered at will. Two pounds per ton of ore of a mixture of coal tar creosote, pine oil and lime, with minute quantities of sodium resinate, has resulted in the production of a concentrate containing over 93 per cent of the copper in the ore.

The mill is capable of handling up to 3,000 tons of ore per day at a total operating cost of 50c per ton, exclusive of Minerals Separation royalty.

No better example of the character and diversity of the problems relating to ore treatment in British Columbia can be cited than is contained in the descriptions of the operations of these three prominent organizations. Metallurgical progress in British Columbia is well illustrated in these outstanding contributions to the proceedings of the Institute. Especially do they illustrate the profound influence metallurgical development now has, and will have to a still greater extent in the future, upon the growth of the mineral industry.

Problems of far-reaching importance are suggested in each of the operations described, and the success of the metallurgist in demonstrating his ability to build up large-scale operations to meet the varied requirements is one of the most encouraging features in the outlook for mining in British Columbia today.

PIG-IRON FROM COPPER SLAG AT ANYOX

The blast furnace slag at Anyox carries 52% iron, a very good iron ore. Mr. H. S. Munroe, manager of the Granby Company, has announced that the metallurgists at Anyox have succeeded in making pig-iron from this slag in a reverberatory, and that there is hope that the process will be commercially feasible.

SILICATE OF SODA IN SOAP

Silicate of soda, which is abundantly available as a by-product from various industrial chemical processes, is now used extensively in the manufacture of soap. It is a mild alkali and therefore is itself a cleanser. It helps to keep soap hard in the presence of hot water. It is much cheaper than the other ingredients, and its use therefore tends to lower the price of soap.

LETTERS FROM READERS

" Not Guilty "

To the Editor,
Canadian Mining Journal.

Mr. F. H. Mason's letter in your issue of October, 19th, under the above title, endeavors to show that the MacKenzie report was not formally published and therefore the press can be excused for not mentioning the matter.

If you will refer to Mr. Mason's letter, published in your issue of Dec. 22nd last, you will find that he writes as follows: "Mr. Campbell avers that our coal reserve has been over-estimated (probably it has,—Mr. J. D. MacKenzie, who has just revised the figures for Vancouver Island, shows that it has, at any rate)." In other words Mr. MacKenzie's conclusions were public property a year ago. If the papers wished to refer to the matter the same source of information was available to them as Mr. Mason used. As a matter of fact one paper did refer to the matter at that time. The papers as a rule, however, were more concerned about a reported find of coal material in Stanley Park than the shortage of billions of tons in the estimated reserves in the area a few miles away.

Now, in regard to the actual report: I received this last June. It was marked "Issued by the Geological Survey, Department of Mines, Ottawa, June 1, 1923." When a report is "issued" it is "published," for the words are synonymous. I do not therefore understand why Mr. Malcolm states that the report has not been published. He probably means that the edition was limited. I do not know why this edition should be limited, for it is obvious that the importance of the report justified a large edition being issued without delay. Whether the newspapers received copies or not I do not know, but I do know that they knew of it, for I advised them myself. I wrote to three of the leading dailies in Vancouver and Victoria, advising them of this report and of its importance. I referred them to the Survey office in Vancouver for further information should they wish to deal with it. Only one of the papers referred to the matter.

Mr Mason's explanation is not, therefore, the correct one.

There is a certain class of company or community whose aim it is to obtain a meal-ticket without working for it. They want the Government to guarantee their bonds or erect expensive works in their town. The basic argument of these people is "limitless resources." There is another class that honestly believes that we have "limitless resources" and will listen to nothing to the contrary. Between these two and the resulting government obligations, the total is now very close to "All up with Squeers."

Within the last 24 hours newspapers have published announcements that work on logging off "the greatest of Vancouver Island's scenic attractions" will start within two months. If there is one disgraceful piece of work which the present generation of Canadians will have to answer it is the wanton destruction of our beauty spots. Before coming to the Island I had heard people rave over the timber near Cameron Lake. To those who had seen it, it was the one thing they remembered above everything else. It is visited by many thousands annually, and tourists not familiar with our trees stop you and tell you what a wonderfully beautifully sight it is.

I consider our present reproachful position is directly traceable to the propagation of the doctrine of "inconceivable wealth," by most of our citizens and newspapers and I propose to do what I an to counteract the baneful influence of that propaganda.

Cassidy, B. C. C. M. Campbell

NEWS AND COMMENTS

By ALEXANDER GRAY

Better Roads to Quebec Gold Fields

As foreshadowed recently, the Quebec Government will provide better transportation facilities for the Quebec gold fields. Provision is being made for a winter road from the end of the Canadian Pacific steel at the Quinze dam, to Lake Opasatica and Boischatel township. From this north and south commercial avenue, lacking which operations have been hindered, another road will be constructed east to Rouyn. The Legislative Council having authorized appropriations for these purposes, the matter may be said to be settled. It is not stated whether other roads will be made from the transcontinental south to the eastern end of the fields. This action will be welcomed as an indication on the part of the Government of its desire to co-operate in a reasonable way with those who are pioneering under difficulties. Most of the winter traffic, it would seem, will be via the Kippawa- Timiskaming line, thence by teams to the mining fields. The Quinze power development, moreover is going to establish more than a mining industry. Already a large grounwood mill is mooted. But power for mines brings a higher price than it will for commercial purposes. That is why the Quinze power people hope to see rapid mining developments — and it looks as if there would be such a development.

Ducal Development of Sisco

A revision of terms is said to have enabled the Duke of Manchester to obtain possession of the Sisco property on Lake De Montigny, which Mr. Spearman has commended because of recent disclosures at outcrop. A certain sum per month is to be expended for a year, and Mr. Sisco is to get so much per month. At the end of a year a cash payment is provided for. Mr. Spearman, who has visited the property and is impressed with its latest aspects, was largely instrumental in effecting the compromise deal, and it is understood he will direct the work.

Sunburst Outburst

Under display headlines, without reservations, the press of New York City and Canada lend their aid to advertising of P. Chester Thompson, "noted geologist," "President of the Royal Canadian Syndicate," erstwhile "foreign scout employed by big American interests", sponsor for the oil development in Columbia, Madagascar and Venezuela, now satisfied that he is leading actor in the exploitation of "the greatest oil field in the world, without exception," in Southern Alberta. The next six months promise to be "most sensational" in the Kevin-Sunburst area, potentially the biggest ever. Right on top of the Sweet Grass Arch, sustained by the results obtained from 100 new wells last year in Montana, P. Chester Thompson is hailed by someone resident in Newspaper Row as Canada's deliverer, just when producers in distress were hoping over-production of oil was nearing its peak or past the peak. Within six months, Mr. Thompson maintains, the Imperial, Standard of California, Producers Refiners (now the Standard), Talpey Arnold, and others engaged on twelve wells, will confirm the newspaper decree that Mr. Thompson is a "noted geologist," as "noted," maybe, as Lord Kelvin, his namesake, was in another place and sphere.

Thus far, in Western Canada gassers predominate. Without detracting from the versatility of Mr. Thompson and wishing him more success than is in sight on this side of the international border, it might be as well to call other expert witnesses and wait their authoritative pronouncements. Undoubtedly progress is being made with local structures; but the knowledge gained is inconclusive.

Mason Valley Absorbs Bluestone

Canadians are at attention because of the deal whereby the W. B. Thompson Mason Valley people acquire the Bluestone property and plant, which Mr. Charles D. Kaeding managed for the late Capt. De Lamar, and where Mr. Dowsett, of the Dome Mines, had charge of the mill during the time the Dome was closed down. Hardly had Mr. Samuel W. Cohen, on behalf of Sir Mortimer Davis and Mr. David Steindler, closed the deal for the Bluestone, in Nevada, when the Armistice left copper metal markets in the doldrums. Canadian money had been subscribed as part payment; considerable copper was in hand; installments had to be forthcoming so soon and no later. The commitment was about a million and a quarter dollars. Messrs. Kaeding and Dowsett did all they are capable of, but the Fates were adverse. There is no need of repeating the details. Messrs. Steindler and Davis could not contend against prevailing conditions. The recent death of Mr. Steindler made necessary, or made possible, the negotiations conducted through Messrs. Poillon & Poirier, Mining Engineers of New York, so well and favorably known throughout the North Country, where they have served in varied capacities, administrative, consultative and operative. Mason Valley capital is doubled to a million shares of $5. The Bluestone Mining & Milling Company gets 246,268 shares for its property and plant. The combination is mutually beneficial. Messrs. Poillon & Poirier have been congratulated upon having arranged the nuptials

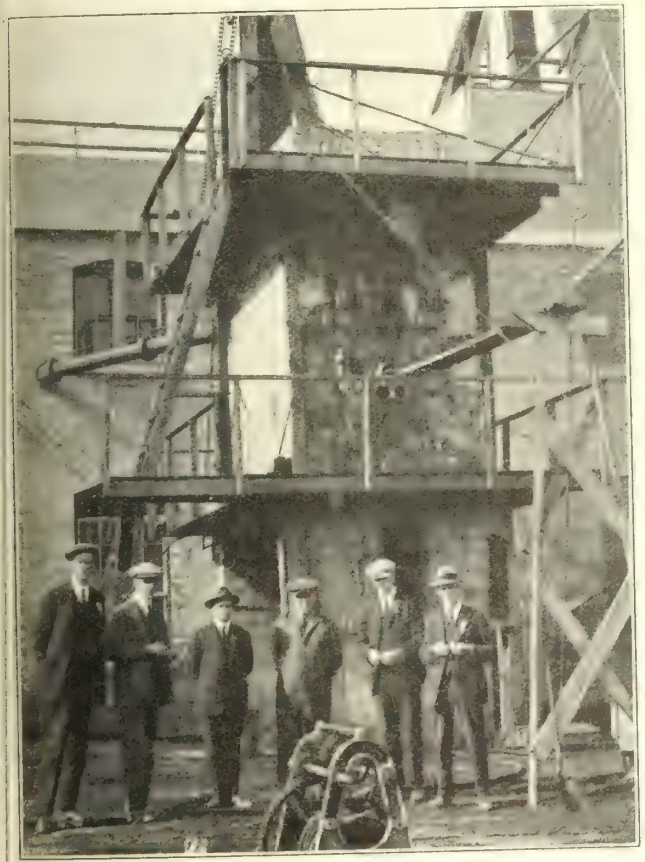
Nipissing in Rouyn

So long as part of Nipissing's surplus of $4,730,404 in cash, government bonds, bullion and ore is to be employed upon other gold or silver properties, it is immaterial whether the company has taken over the Powell area in Rouyn township, Quebec, or something else that the executives deem worthy of a try. The first rumors were that the Noranda had been acquired. Now it is said it is the three Powell claims, which the Noranda dropped, and where considerable work was done, with interesting, if insufficient, results, in view of the purchase price. If Messrs. Watson and Knight have a mind to make an effort in Quebec, it can be accepted that Quebec deserves it. Nipissing has tried to find "another Nipissing"—but they are hard to find. It requires something out of the ordinary to measure up to Nipissing standards. With Nipissing's hall-mark on something new, and good enough for Nipissing chiefs, the Northland would be given a boost that would mean much to it

LIGNITE CARBONIZING FURNACE IS SUCCESSFUL

The central item of the Annual Western Meeting of e Canadian Institute of Mining and Metallurgy held Estevan, Saskatchewan, last month was the inspec- n of the lignite beds in the vicinity of Souris and lenfait and across the border in North Dakota. ese beds of lignite constitute one of the principal serves of fuel on the continent, though their present efulness is restricted by the high content of mois- re and the tendency to break up on shipment and exposure to the air, as well as the liability of the ned product to spontanous combustion when stored long periods.

The Lignite Utilization Board of the Dominion and skatchewan governments (Manitoba has dropped t) have recently operated successfully at Bienfait e modified Hood-Odell carbonizing oven shown in e accompanying photograph. This is a simple brick



odified Hood-Odell Carbonizer at Bienfait, Sask. In the reground are the Secretary and members of the Institute. the background is the building housing the former plant of the Lignite Utilization Board.

ack into which raw lignite is fed continuously at the p, lignite char being discharged at the bottom. ombustible gas from the top of the stack and air e introduced, also not far below the top and the aseous products of combustion are collected and may treated if desired for the recovery of by-products. he partial combustion of the lignite thus simply effec- d removes the volatile matter sufficiently to give a iable charcoal-like residue, which makes a first-rate uel when compacted by briquetting. Instead of ex- ending the money necessary to install an experimental riquetting plant the Lignite Utilization Board have ecided to send some of the char to Hebron, North Da- ota where the United States Bureau of Mines has a suitable plant already installed and available for the Canadian experiment.

The Hood-Odell carbonizer, as installed at Bienfait, is a simple brick stack of square cross-section with a hopper-like bottom. Screened lignite of nut size is fed at the top, and in its descent is stirred up by means of air-cooled pipes placed across the interior of the stack. Drying and carbonizing are effected by the simple expedient of passing ignited gas across through the top of the stack, a maximum temperature of 1200 degrees F. being attained. As the ignited material continues downward through the stack its temperature is reduced below the point of ignition, and the char is discharged periodically through a gate at the bottom. The char is light and friable, much like charcoal, and contains 10 to 15% volatile against 38 to 40% in the raw lignite. This small experimental unit gives 10 to 12 tons of char per 24 hours.

As could be expected from the nature of this operation, the yield of by-products is small compared with a distillation process. At present about 35 pounds of tar per ton of lignite is recovered, which contains 65% pitch and 35% oils the latter being 35% creosote. The pitch thus recovered is one-fifth of that required as a binder in briquetting the char, and will have to be supplemented by pitch from other sources. Experiments are now under way with a view to separating the pitch from the tar.

The gas drawn off from the stack has a low calorific value, but the quantity available beyond that required for burning again in the stack is equivalent to three tons of lignite per day and it can be used economically to raise steam or for similar purposes. Its analysis is approximately:

carbon dioxide	12%
carbon monoxide	12%
hydrogen	11%
methane	3%
nitrogen	62%
	100%

It is estimated that the briquettes can be turned out at a total cost of $9.50 per ton. If that should prove to be the case, this excellent manufactured fuel will compete in Winnipeg, the nearest large market, on favourable terms with high-grade domestic coal from Alberta, which now virtually holds that market. Drumheller coal at present costs $4.50 f.o.b. cars, and the freight rate to Winnipeg is $4.80. Saunders Creek coal costs $6.00 on the cars, and the freight is about the same. Saskatchewan lignite costs from $ 2.10 to $2.50 for run-of-mine, and $3.50 for selected lumps, on the cars and the freight rate is $2.40, and a good deal of it is being shipped to Winnipeg during the fall and winter months.

It appears that now, at last, a simple and effective method has been found to turn the lignite into a first-rate fuel. When this shall have been demonstrated fully, Saskatchewan's fuel resources will become at once immensely more valuable.

The output of coal in the United States for the first ten months of 1923 is 456,728,000 tons, which exceeds all previous outputs except that for 1918, which was 489,239,000 tons for the corresponding period.

Engineers and the Proposed B. C. Steel Plant

Western Members of the Institute Endorse Unanimously the Report of their Executive

A representative expression of the opinion of the West's technical men on the proposals of the promoters of Coast Range Steel Ltd., was given at the business meeting of the British Columbia Division of the Canadian Institute of Mining and Metallurgy, held at Rossland during the annual meeting last month. The Executive Committee of the Division took advantage of the occasion to obtain endorsation of their action in voicing a warning in regard to these proposals.

The subject was introduced by the Chairman, Mr. Thomas Graham, who called upon the Secretary to give an account of the steps that had been taken by the Executive, Mr. H. Mortimer-Lamb recounted the meeting of a special Committee with Mr. Landahl, when he promised to give every assistance to the Executive of the division in investigating his scheme. Mr. Lamb went on to state that he had attended a meeting of the Victoria Chamber of Commerce upon the instructions of the Executive, and described Mr. Landahl's subsequent rescission of his offer to assist the investigation of the Executive Committee. Mr. Lamb stated that the Committee had been taking active steps to secure authoritative views upon all the salient points of the project, and he then read out to the meeting a letter he had addressed to the Premier of British Columbia on behalf of the Executive. The letter was as follows:—

Letter to Premier Oliver

12th October 1923.

"The Hon. John Oliver,
Premier of British Columbia,
Victoria, B.C.

"Dear Sir:

"By virtue of its charter granted by Act of Parliament, the Canadian Institute of Mining and Metallurgy as a national organization representative of the mining profession and industry of Canada, has always sought to avail itself of opportunities to act in an advisory capacity to the Governments of Canada to which it owes responsibility in the service of the mining industry of the country.

"The British Columbia Division of the Institute has for some time past interested itself in the question of the establishment of an iron and steel industry in this province, and ardently desires to assist in any movement towards that end having a justifiable basis. In evidence of this desire the action of the Division may be cited in recommending last year to the Honorable the Minister of Mines, the advantage of securing the co-operation of the Dominion Geological Survey to determine more definitely the iron ore resources of the Province. We believe that the results of this investigation will, in due time, indicate the existence of resources that will form a valuable asset, and that the position of British Columbia as a producing and manufacturing Province may reach proportions that can hardly be gauged by the present situation. We look forward to the possibility of an iron and steel industry in British Columbia founded on proven facts and justified by industrial conditions yet to materialize.

"For these reasons the Executive of the Divis views the problem of an iron and steel industry one of such moment to the welfare of the Province a as being fraught with such ultimate possibilities a fecting its standing in the eyes of the world as to c for the greatest possible care in the matter of presentation, but regards with grave distrust t proposals of Coast Range Steel Limited in which appears that the endorsement of the State is c sidered to be necessary to the acceptance of c jectures upon yet unproven statements and calcul tions.

"The Executive has devoted considerable time to t consideration of information regarding the salie features affecting pig iron production and witho further reference to the question of the supply of ir ore than is implied in the evident desirability to awa the report of the Geologist employed by the Domin Government at the instigation of the Hon. the M ister of Mines to investigate the resources, it h concluded that the main criticism of the proposals Coast Range Steel Limited, may be summarized general terms as follows:—

"There are no reasons for supposing that pig ir could be produced in British Columbia any cheape than it is now being produced at established centre and therefore, the opportunity for competition in th open market is problematical, while the local mark must rely upon possible future developments to absor the product of a plant such as is proposed.

"The whole scheme therefore depends for its just fication upon future developments and not upon ex tent facts.

"The Executive feels called upon to voice its co sidered opinion that it is not in the interest of th country's credit any more than it is to the interes of the tax-payer to embark upon an undertaking th in its essentials amounts to a gigantic proposal f discounting future possibilities.

"On the score of finance the following consideratio are added:

1.—Any proposition requiring guarantees coveri the entire capital must be inherently unsound.

2.—If a proposition is economically attracti capital is usually available for it without Gover ment guarantees.

3.—Under such conditions capital requires reaso able proof of the attraction, and a Government cann give financial assistance upon less assurance of s curity than would be required by the private invest

"The character of the liability proposed by Coas Range Steel Ltd., is not such as to warrant its being incurred by the Provincial Government at this time and especially in view of the fact that iron and steel industries in Eastern Canada, where natural cond tions are at least as favorable as in British Columb and market conditions eminently more so, have ofte failed to show a profit despite Government assistance.

"The Executive desires respectfully to submit these views for your consideration with a request for your sanction to publish this correspondence in the publ press.

"The Executive, on behalf of the Institute, will be

most happy to place its service at the disposal of the Government in any further investigations of this matter.

"The members of the Committee subscribing to this letter are, Mr. Thomas Graham, Chairman; Mr. H. G. Nichols, Mr. F. W. Guernsey; Prof. H. N. Thomson; Mr. Nichol Thompson; Prof. W. L. Uglow; Mr. H. Y. Russel; Mr. S. J. Crocker, and Col. J. E. Leckie.

I am, dear Sir,

Yours faithfully.

(Signed) H. Mortimer-Lamb.

Engineering Judgment the Basis of Conclusion

The Chairman then called upon Mr. H. G. Nichols to explain the attitude of the Executive in this matter. Mr. Nichols said that the attitude of the Executive had been that of an engineer called upon for an opinion upon a proposed investment. In such cases, the engineer has to get his facts first, and his judgment and experience may only be applied in the manner and to an extent justified by such facts.

In regard to iron and steel production, all those present had been aware of certain natural conditions of a sufficiently encouraging nature to demand investigation, to the end that facts might be established upon which some opinion might be formed, and a scheme outlined that would be in keeping with the present outlook. When the promoters of Coast Range Steel Ltd. put forward their proposals, it was thought at first that they must have made such an investigation and secured such facts, but enquiry proved this not to be the case, and it was then that the Executive felt called upon to express its distrust of the scheme, especially as it was based upon State guarantees.

The Executive did not criticise the promoters of Coast Range Steel Ltd. for their optimism in regard to the future of British Columbia; that was not their exclusive prerogative. But the Executive might be excused for some astonishment at the facile methods by which certain well recognized possibilities had been transformed into arguments in favor of a great financial undertaking. They were not the methods of sound technical advisers. Mr. F. W. Guernsey also spoke for the Executive, and said that his own conclusion had been directed by an entire disagreement with the financial considerations connected with the scheme. Several members expressed warm approval of the action of the Executive and a resolution was carried unanimously endorsing it.

EXPLORATION IN GILLIES LIMIT

The success at the Keeley and Frontier silver mines in South Lorrain, Ontario, has stimulated exploration in several adjacent areas with similar geological formations. For instance, a syndicate has acquired an area of over 300 acres covering the Keewatin-diabase contact in the vicinity of Borden and Botha lakes, in the southeastern part of Gillies Limit, and is engaged actively in exploring the ground. Trenching during the past summer has disclosed two veins of calcite containing cobalt bloom, in diabase. It is proposed to follow these veins to the contact with the Keewatin greenstone, several hundred feet underground, in order to find whether or not a concentration of silver values such as that found in South Lorrain and at the Beaver and Temiskaming mines has taken place here also. The project has been endorsed by responsible engineers familiar with the Cobalt district.

PROGRESS AT LORRAIN TROUT LAKE MINES

Another silver producer in South Lorrain is foreshadowed in the progress report submitted last month to directors of the Lorrain Trout Lake Mines, Ltd., (held largely by the Mining Corporation) by the manager, M. F. Fairlie. The report, in part, follows:

Shaft Sinking—This was continued as a prospect shaft following the Woods Vein to a depth of 275 feet. Down to this point no water had been encountered and fortunately pumping apparatus was unnecessary. This is now required, and, while the equipment is being installed, drifting North and South has been started at a depth of 240 feet.

Results in Shaft Sinking—At the present depth of 275 feet the rock formation is still keewatin, though the underlying diabase may be reached within the next 75 feet of sinking.

The Woods Vein as exposed in the shaft continues to maintain its remarkable strength,—it's width varying from 3 feet to 6 feet between walls. It is much brecciated and altered and oxidation is still in evidence at the shaft bottom. The footwall section of the vein, with a width of 10 inches to 24 inches, is largely crushed and decomposed smaltite carrying varying values in silver. In same places very high-grade silver has been exposed, but these showings have been avoided in channel sampling.

Results of Sampling in Shaft—[Forty-six samples at five-foot intervals show the vein from 4 inches in width, assaying 321½ ounces, to 54 inches wide, assaying 64.8 ounces, the average width sampled being 22½ inches. The assay samples run as high as 2214 ounces across 19 inches, though very high-grade ore was excluded from samples.

Results in Drifting—The only lateral work so far done is at the 240 foot level, where drifts North and South from the shaft have been started. The North drift at this date is advanced 44 feet and the South drift 36 feet. The total of 80 feet of drifting shows the same average width and apparent assay values as the shaft. Sampling results will be available in about one week's time.

Surface Trenching—Several transverse veins have been exposed by surface trenching and are shown on the accompanying Surface Plan. Exploration of these veins will eventually be carried out under ground.

Future Operations—Shaft sinking will be continued in the course of a few days and carried at least to the diabase contact. It is of interest to note that the present shaft bottom at 275 feet is more than 200 feet above the 7th level of the adjoining Keeley property.

Conclusion—The values disclosed in shaft sinking and drifting are remarkably consistent for the South Lorrain District and, in view of the altered and oxidized condition of the vein, there is great promise for the future development of high grade ore at greater depth.

The area so far opened up will permit profitable extraction of mill grade ore for the full vertical distance from the surface.

HIGH LABOUR COSTS PREVENT EXPORT TRADE

A recent American visitor to Australia has stated his opinion that the Commonwealth will never be able to work up much of an export market in metals, due chiefly to high labour costs. High wages and the prevalence of the 35-hour week are chiefly responsible for this.

ALL-SLIMING AND BLANKET CONCENTRATION

In his report on 1922 operations on the Rand, the Government Mining Engineer, Sir Robert Kotze, makes the following remarks about recent metallurgical practice:

The innovations at the Springs Mines reduction plant have now been in operation for some months, and, so far, the results have fulfilled the anticipations of the engineers, who, after searching experiments and investigations, had the courage to spend the money in putting their ideas into actual practice.

In the new portion of the plant the old-fashioned gravity stamps, which have survived from the earliest days of these fields, have been entirely discarded, being replaced by ordinary stone crushers with slight adjustments. The crushed product is fed directly into tube mills, and eventually all reduced to slime, which is cyanided in the usual way, sands treatment being entirely eliminated. The tube mill product is classed in a Dorr classifier, the first of its kind on these fields, which is a marvel of simplicity and efficiency for this special purpose.

As a result of a few months' working, the designers of this plant make the following claims, viz.:—

1. Reduced capital expenditure is estimated at 30 to 35 per cent.
2. Reduced working costs, due to elimination of the staffs usually employed on amalgamation and sands treatment. A considerable saving is also effected in pumping the pulp, which, as slime, naturally has less wearing effect on the pump blades. The treatment of slime is also admittedly cheaper than in the case of sands.
3. Increased extraction of gold, due to the greater fineness of the treated slime as compared with equal units of the old plant. the figures in this connection are 78 per cent, under 200 mesh, as against 58 per cent. in the old plant. The extra fineness gives a higher extraction with correspondingly lower residues.
4. Decreased loss of gold through theft, owing to entire absence of amalgam and the comparatively simple manner in which all the vital processes of reduction can be assembled under one roof, with closer supervision.

The practice of abolishing the usual amalgamation procedure on battery and tube mill plates is rapidly spreading. A coarse corduroy cloth is now spread on the tube mill tables, which efects a concentration of the heavier particles in the pulp, which are washed out in launders every two hours. These concentrates are subsequently further concentrated on Wilfley tables, and the final product caught in amalgamating barrels or other similar contrivances. At one large mine in the district where this practice has been recently adopted the residues have been brought down by 0.04 dwt. per ton, a very considerable saving over a large tonnage. It is further claimed for this practice that the chances of theft of gold are considerably minimised. Special arrangements are also made on this mine for recovering platinum iridium, the recovery being close on 20 ounces per month.

It is reported that gold on a payable scale has been discovered at Yanawai, Vanualovu, in Fiji, giving a yield of 54 ounces from 35 tons. The Government have asked New Zealand for the loan of a mining geologist to advise on the question of working the area.

USES OF RUBBER IN THE MINING INDUSTRY

by Q. E. F. in The India Rubber World

Much has been written in recent years regarding rubber surpluses and the need for new uses of rubber. In the latter direction much has been proposed and considerable accomplished, yet only the more obvious possibilities of rubber seem to have been seriously considered. It is also a curious fact that the most original proposals for the use of rubber come from persons outside the trade. While many such suggestions are admittedly impractical, the mere fact that a suggestion is revolutionary should not condemn it until it has had a fair trial and failed. Such a trial has time and again resulted in the birth of a new line of rubber goods. As time goes on we shall undoubtedly see the development of innumerable new uses of rubber, many of which will not singly consume a great quantity of rubber, but in the aggregate will greatly swell the total consumption.

Basic Industries Should Be Studied

It is an unfortunate tendency of many manufacturers of rubber goods, as in numerous other fields, to follow along their accustomed rut, apparently wearing smoked sheet glasses, confining themselves to their regular line of products, and lacking the vision to extend and reapply them to new fields of industry and popular usage. Somehow the man in another industry too often senses the practical application of rubber to it before the rubber man does. Possibly this may result from the present tendency toward quantity production of a limited line of products. It may be good business but it does not make for progress. Certainly it presents an opportunity for new concerns to gain a foothold in the rubber industry.

To find practical new uses for rubber requires systematic investigation, a lively imagination, an open mind, and a willingness to experiment. Thus far most of the newly suggested uses of rubber have been evolved in haphazard fashion, but the time seems near at hand when the research departments of progressive rubber concerns will comb thoroughly one by one all the great industries, process by process and machine by machine, in search of ways in which rubber may serve better than the materials now in use. And in this campaign the voluntary suggestions of experts in the various industries may prove quite as productive of revolutionary applications of rubber as the investigations of rubber men.

Ball Mill Linings

For example, take mining, a basic industry supplying the raw materials for numerous lines of business of world importance. Just as rubber lined ball mills[1] are already demonstrating their numerous advantages and general superiority over steel lined mills,[1] so the mining industry offers numerous opportunities for the successful application of specially designed rubber goods, either to supplement the devices already in use or to supplant them altogether. The following suggestions are made with emphasis on the fact that a mine manager or mill superintendent is continually striving to save a fraction of a cent per ton of ore mined and milled and to do so is ever ready to adopt a new product or adapt an old product to a new use.

Possible Uses in Handling Ore

Following ore from its source deep in the mine through the mill discloses several ways in which rub

[1] Canadian Mining Journal Aug 10th 1923

ber might be applied advantageously. Ore blasted out in the mine is conveyed to the crushers in cars of steel or iron. The life of a car is short owing to the heavy wear of rock on steel in filling and dumping. Rust, due to water in the ore, hastens the disintegration. Cars with rubber lining to take the blow of the ore would reduce the cost of mining by making them last longer. Moreover, the water in the ore will wet the rubber, rendering it almost frictionless and prolonging its life for the present purpose.

The car of ore is rolled along to the dump at the crusher. Some cars are tilted and banged against a steel or wooden bumper, which damages the car and wears out the bumper. A rubber bumper would save the car and reduce costs.

After the ore is dumped it frequently slides down a metal chute, which wears rapidly, especially where there is much water in the ore. But this water would make the ore slip down a sheet of rubber with little wear, saving time and money.

If the ore goes into a bin it usually comes out on a feeder. Some of these feeders are rubber covered belts, but others are just chutes. A metal covered belt would not last long enough to mention, but a rubber covered belt does. Where the ore slides out of the bin why not line the chute with rubber?

The crushed ore is fed onto a concentrating table covered with linoleum, probably because linoleum manufacturers have been better salesmen than rubber manufacturers. If a concentrating table was ever properly covered with rubber and the rubber discarded in favor of linoleum it was the rubber manufacturer and not the rubber that failed. These table tops are covered with little strips of wood nailed on with copper tacks. When the linoleum is to be replaced all these wooden strips and tacks must be removed, and it is a lengthy job. Linoleum manufacturers are making ribbed strip coverings for automobile running boards. It ought to be possible for some rubber manufacturer to make a molded rubber top for concentrating tables that will eliminate the wooden strips. These strips are placed in various positions by table manufacturers, but there may be enough of any one kind to make molded rubber coverings profitable.

If rubber lined pumps, rubber lined ball mills and rubber covered belts outwear steel, why not use rubber in other work where abrasion is an item to be considered in costs. For example, rubber lined pumps are commonly forcing abrasive materials into metal pipes which must be replaced frequently, especially at the elbows. How about rubber lined elbows and pipe? They might cost too much, but that ought to be figured out by actual test.

The Basis for Wider Applications

Carrying this principle into a wider field of usage brings a thought regarding ash handling. Ashes propelled by steam are lifted out of buildings and boats through metal pipes, but the ashes cut away the bends. A rubber lined bend wet with a small jet of water to lubricate it would probably outwear any metal in existence.

In general it may be confidently said that any place in a mining or milling operation where ore strikes against or slides on metal, especially when wet, or where iron, steel or wood is used to protect something from abrasion, is a prospective place for the use of rubber, bearing in mind that rubber at 60 cents per pound is equal or better than steel at 13 to 14 cents per pound. It can be molded to fit any conceivable place, and when the proper compound is used it will outlast any other material.

ANNUAL REPORT OF ANGLO-CANADIAN EXPLORERS

English Company Represented in Canada by A. D. Miles acquires three properties during its first eight months of operation

In presenting to shareholders the annual report of Anglo-Canadian Explorers at the first annual meeting in London on October 16th, the chairman, Hon. Lionel Holland, said:

The nominal capital of the company is now £125,000, in £1 shares, and of these some 100,000 odd have been issued—all subscribed for cash—with 7s. 6d. a share remaining to be called up as funds are needed. Formed some fifteen months ago as a private company, with a capital of £65,000, it soon became apparent that the company had entered a field of large possibilities, which every month were attracting more and more the attention of the mining world. We had been successful in establishing an efficient exploratory and mining organisation in Ontario; we had secured, in Mr. Miles, a representative of first-rate mining experience and reputation, efficient and reliable, intimately acquainted with the district, and he is assisted by a small but thoroughly competent geological and engineering staff. Thus our organization and management have won the confidence of mining people in Ontario, so that prospectors and owners of mining concessions have realized that this company is not out to snatch a hasty profit, or to do a deal in shares, but rather to test thoroughly properties that it takes in hand, with the one aim of discovering mines of real commercial value.

250 Gold Properties Examined

In this way the company was put into a position to pick and choose among a wide range of properties—obtained a choice of options upon terms that may be regarded as reasonable, and for periods that admit of the work needed to test the areas under option. You will appreciate the magnitude of this mere business of selection when you note the information in the report—how over 250 gold mining propositions in Canada had been submitted to Mr. Miles by the end of last March, although I need scarcely add that only a small proportion of these have been transmitted for the consideration of the board and managers in London.

Although, then, we have enjoyed—and, as yet, still enjoy—so favourable an opportunity for taking up likely options, competition in the mining fields of Ontario is becoming more keen, and capital—especially capital from the United States—is being attracted to these areas, which were visited a few months ago by some 200 members of the American Institute of Mining Engineers. We thought it very desirable, therefore, with the assent of our shareholders, to increase the capital of the company by another 60,000 shares, so that we might be in a position to take options at once over more properties than our original capital admitted, and to have the funds needed to test their value. Our issued capital is now, as I have mentioned, over £100,000—all subscribed for cash. There are no vendor's shares, and we hold a balance of over 24,000 shares unissued.

Seven Properties Under Option

This capital will suffice for our present aims and requirements, to take under option a limited number of selected areas, and to complete all the exploratory work necessary to test these areas and prove their prospective value as mines—in short, to proceed with our work on a scale

that, I hope, may result in valuable discoveries. On the other hand, the available capital by no means exceeds the requirements of our programme. We have still to be careful not to spread our activities too widely, but to concentrate our serious development work and expenditure on such few selected properties as appear to show the best promise.

Of the forty mines, or mining areas, that our engineers have up to now examined, we finally took options over seven, in order to proceed to prove their value further by diamond drilling and other preliminary development work. Three—I think I may now say four—of these we are not proceeding with further. The results of our testing work were not sufficiently encouraging. But this, of course, is far from meaning that these properties, over which we have resigned our options, have no value, that they may not ultimately be developed by expenditure upon deeper operations into mines of commercial value. It means only that we are not possessed of the purse of Fortunatus, and must apply our resources in the first instance to properties where surface indications and discoveries at the higher levels are the most promising. Had we indeed an inexhaustible purse, chances of success as inexhaustible appear to be offering in the enormous area of the pre-Cambrian rocks of Canada.

Three Option Taken Up

The report informs you that we have now in hand three properties—the Queen Lebel, the Gull Lake, and the Kirkland Townsite—all on the Kirkland Lake field. In the Gull Lake mine we have a third interest in a company registered in London, with a capital of £60,000. Over the Queen Lebel and Kirkland Townsite properties our company holds options for periods which will allow of a thorough examination. The work on all these properties is well in hand. Already good progress—exceptionally rapid—has been made with sinking a shaft and some crosscutting on the Queen Lebel area, where a surface break or lode exposed is considered one of the best in the district. Two diamond drill holes have been going down on the Kirkland Townsite area to locate the site for a shaft, and a plant for sinking the shaft will be delivered on the property this month or early next month. The London Gull Lake Co. is already clearing the ground and trenching, preparatory to commencing underground work.

We shall take up two or three additional options. Our engineers are now engaged upon examining three or four other properties, where the surface indications and other appearances are encouraging. We have, besides, ventured a bit further afield from the Kirkland Lake and Porcupine districts, and have staked some claims on our own account in an undeveloped territory further to the west in Ontario, where surface features and showings of gold are promising, although we do not contemplate undertaking work of any consequence on these claims at present.

Progress at Kirkland

Generally, I may say that our technical advisers—our representative in Canada and our managers, Messrs. John Taylor & Sons, here—view our prospects most hopefully, and a visit just recently paid to Ontario by Mr. Kenneth Taylor and our admirable secretary, Mr. Bayley, serves to confirm this view. They have returned more than satisfied with the efficiency of the organization that Mr. Miles has established on the field, and with the likelihood of successful results. Of course, our venture is a mining speculation, but a speculation of unusual promise, with unusual possibilities of profit. Our options are situated in proved goldfields—fields of increasing importance. The production of the Kirkland Lake area for the first six months of this year is almost equal in value to the total production for the twelve months of 1921—a value, roughly, of some £300,000 for the six months, compared to £325,000 for the twelve months of 1921; or, to compare results with last year, in the twelve months of 1922 gold to the value of £460,000 was produced—in the first six months of this year to the value, as I have said, of £300,000. Then in the Porcupine field, as you will know, the Hollinger mine ranks now as the third largest gold producer in the world. Taking the whole of Ontario, the gold production for the twelve months of 1922 was of the value of £2,143,500 odd, whereas for the first six months of 1923 it valued over £1,883,200.

We hold our options in the neighbourhood of producing mines, yet on a field only recently taken in hand at all seriously with adequate skill and capital. Although the winter there is severe, yet underground mining is continued right through the year, and it is a field that lends itself to economial development. Our areas are being selected with caution—picked areas; we shall test them thoroughly, and make no attempt to exploit them until satisfied upon their prospective value as mines.

PERSONAL AND GENERAL

Mr. W. C. Wallin, superintendent of the coke ovens at Sydney, is on a visit to the Pittsburg district where he will make a special inspection of coke oven plants. Mr. Wallin visited England a short time ago for the purpose of learning the latest in coke production in that country.

Mr. John A. Swanson has been appointed superintendent of the Hidden Creek mine at Anyox, B. C. in succession to Mr. J. Tuttle. Mr. Swanson has been with the Granby Company since 1898, when operations at Phoenix were just commencing. His assistant will be Mr. W. Coulter, who has been with the Company since 1914.

Mr. Frank Carnegie is in charge of operations at the old Foley mine near Mine Centre in northwestern Ontario. The mine workings are being unwatered and sampling is proceeding as the waters recede.

Dr. A. R. Ledoux died at his home in Cornwall-on-Hudson on October 25th. Dr. Ledoux has been, for many years, an international figure, known to a large number of Canadian miners and metallurgists, both personally and professionally. He was seventy years old.

Mr. P. E. Fisher, President of Pacific Coast Pipe Co. Ltd., Vancouver, B. C. died at Seattle Wash. on October 21st. He was born in New York 57 years ago and went West in 1903. In 1904 he organized the Pacific Coast Pipe Co. in Vancouver, B. C. and similar companies in Spokane and Seattle, Wash., and later in Portland, Ore. He disposed of his Seattle and Spokane factories about ten years ago and sold his Portland plant to American interests, centering his activities on the Company at Vancouver.

WORLD PRODUCTION OF COAL

During the first six months of 1923 the world production of coal was 660,000,000 tons, an increase of 79,400,000 tons or 13.3 per cent. over the first half of 1922, according to data published by the United States Geological Survey. Canada's quota is 4.12 per cent. of the total.

METAL MARKETS

Average for week ending Nov. 3rd.

Prices in cents per lb. as quoted by Consolidated M. & S. Co.)

Electrolytic Copper, per lb.	14.50
Zinc, per lb.	8.00
Lead, per lb.	7.57

THE MINING DISTRICTS

NORTHWESTERN QUEBEC

Progress on Noranda. — Reports from the Rouyn District of Northwestern Quebec indicate that the Noranda find is of very substantial promise. Recent work has proven a surface area 100 feet wide for a length of 300 feet, with a further indicated length of approximately 400 feet. The average value for this area is understood to be over $5.00, while sections on each side run much higher. A shaft has been started and is down approximately 25 feet. A small mining plant is being installed and the shaft will be continued to about 150 feet, at which point lateral development will be undertaken. During the winter it is proposed to diamond-drill the property. On the Horne group, which is also under option to the Noranda Company, the first diamond-drill hole gave about 7 per cent. copper and about $6.00 in gold across a width of 100 feet. Later holes did not substantiate these results, and now it is proposed to drill a number of vertical holes.

Improved Transportation Service. — Transportation into Rouyn during the coming winter will be improved. A road is to be built from the end of the steel at the Quinze dam, which will be approximately 70 miles in length. This road will effect a very substantial saving in the transportation of freight and supplies, and instead of costing about $150 a ton, as was the case last summer, the freight rate should be cut to about $50 a ton. It is also proposed to start preparations for a much improved transportation service next summer. During the past season gasoline boats were used on the rivers and there were a great many delays and breakdowns. Next year it is proposed to use small steamers, which it is believed will provide a more economical and efficient service.

Smaller Claims Recommended. — The Quebec Government is considering the advisability of changing its mining laws, particularly with reference to the size of the claims. Under the present Quebec law, prospectors can stake claims containing 200 acres, and by the use of a number of licenses can stake practically as many claims as they desire. While it is advisable to have a mining area of approximately 200 acres, the great size of the holdings in the Rouyn section has been a disadvantage in the development of the district. Companies taking options were given a much greater acreage than they could properly develop, except at a prohibitive expense, and as a consequence very few companies have taken up the whole of their ground. If the holdings had been in smaller blocks there is little doubt that more prospecting work would have been done and possibly more discoveries made.

REPORT ON WATABEAG AREA

Recently the publication of the map of the Watabeag area in northeastern Ontario was noticed in these pages. There has been published now Mr. D. G. H. Wright's 30-page report on this area, whose geology is in the main similar to that of the adjoining Porcupine and Kirkland areas. It constitutes Part 7 of the 31st report (1922) of the Ontario Department of Mines.

NORTHERN ONTARIO

Cobalt. — A good deal of interest has been aroused in Cobalt by the discovery of an immense float nugget in the Gillies Limit. It is the largest piece of float ever found in the history of silver mining in Northern Ontario, and weighs over a ton and contains approximately 18,000 ounces of silver. The largest nugget found prior to this was on the Silver Gem property, and contained 9,715 ounces. This nugget was purchased by the Ontario Government and is on display in the Parliament Buildings in Toronto. The latest discovery was made on a claim belonging to New Liskeard people, which is located in the same vicinity as the properties in the Limit which the Mining Corporation has under option. Its discovery has greatly stimulated interest in this section. The surface geology of the claim on which it was found consists of Keewatin greenstone overlying the diabase, and the rock adhering to the nugget also consists of Keewatin greenstone. While there is a possibility that the nugget may have come from a vein in the comparatively close vicinity, it is probable that it was derived from veins further to the north and carried down by the glacier.

Prospectors are showing a good deal of activity in Gillies Limit, and several mining companies are also investigating properties there. The Mining Corporation has let a contract to sink its shaft, which is now down approximately 50 feet. The shaft will be continued close to the contact, and in order to determine the depth to which it will be necessary to sink, a diamond-drill hole will be put down. The shaft is being sunk on a vein which in places carries several inches of smaltite, with low silver values.

La Rose is considering the development of the Fisher-Eplett property, which lies to the North of the Beaver. A number of years ago a shaft was sunk to a depth of 300 feet, in one corner of the property, and work was done on one vein. The results were not particularly encouraging, but as it has now been determined that the contact lies at a depth of approximately 500 feet, it is believed that greater possibilities will exist near the contact. A large portion of the property, containing strong surface veins, has not been explored.

Nipissing Exploration. — The Nipissing has been very active this Fall in exploring for new properties. At present the company's engineers are examining properties in the Rouyn district, particular attention being given to that portion of the Noranda group containing the Powell vein, and consisting of four claims. The Powell vein was the original discovery in the district, surface assays giving promising values. Aside from a few test pits, surface work and diamond-drilling only were done by the Noranda company, and since the latest discovery made on the southern part of the property, the company has confined its attention to this latter. The Noranda has a very large acreage, in which there is plenty of room for both the Noranda and the Nipissing to operate. The Nipissing has recently

staked three claims under the waters of Lake Temiskaming, in the South Lorrain area. The claims are located near Silver Centre, and are supposed to contain a continuation of the veins on which the Maidens work is being done. The Maidens is under option to interests associated with the Keeley, and is being developed by them. Accompanying the Nipissing dividend cheques was a financial statement, showing current assets as of September 29th amounting to $4,730,000. Of this amount, ore and bullion in process, on hand and in transit amounted to $543,000, the balance of over $4,000,000 being cash in the bank, bonds and investments.

South Lorrain. — The Mining Corporation continues to meet with favorable results in its development of the Trout Lake property. From the 275-foot level of the shaft, drifting has been carried for about fifty feet each way, with good milling values and some high-grade. Contrary to the general experience in the South Lorrain district, continuous ore was found in the shaft for almost the total depth. A particular point of interest in connection with this property is the fact that the 275-foot level is over 200 feet higher, in a geological sense, than the 7th level of the Keeley mine, which has been such a phenomenal producer. The Mining Corporation has also encountered some new ore on the Peterson Lake property. The veins, while small, are of fairly good grade, and a considerable tonnage of mill ore is being broken.

Porcupine. — Accompanying Dome dividend cheques, dated October 20th, was an announcement that on and after November 14th, shares were to be forwarded to the Empire Trust Company, New York, in order that new certificates might be issued in the ratio of two shares of no par value for one share of the old stock. The financial statement accompanying the dividend cheques shows that for the six months ending September 30th, the gross profits amounted to $1,375,000, from which was deducted tax reserves of $69,000, and plant depreciation and mine exhaustion of $299,000, leaving net profits for the period of $1,006,000. The balance sheets shows current assets of Bonds, $1,153,000; Dividend Assurance Fund, $1,059,000; Loans on Call, $1,250,000; Accounts and Interest Receivable, $45,000; Inventories, $341,000; Bullion in Transit, $80,000; Cash, $195,000. Current Liabilities consist of, Accounts Payable and Tax Reserves, $340,000; and Dividends Payable, $485,000. The reserve for plant depreciation and mine exhaustion stands at $3,504,000. Surplus is shown at $1,138,000.

At the March property, in Deloro, drifting is being done on the 800-foot level. The company reports that the veins carry satisfactory values.

West Shining Tree. — Officials of the Westree property in Shining Tree report exceedingly high assays from diamond-drill holes. The Tonopah Mining Company of Nevada has taken an option on the property, and will continue its development.

NEW HELIUM PLANT

It is proposed to bring up a bill at the next session of Congress to authorize the expenditure by the United States Bureau of Mines of $5,000,000, to purchase helium-bearing natural gas and gas fields. A new helium extraction plant on a semi-commercial scale will be put in operation shortly at Fort Worth by the Bureau of Mines. It is expected that this improved process will produce helium at much less cost than former processes.

BRITISH COLUMBIA

Anyox. — The Granby Consolidated Mining & Smelting Co. are reported to have dropped their options on an iron pyrites property situated on the Extall River and on the Sultana Group on Portland Canal. On both exploratory work had been done, the development on the Extall River deposits having extended over a considerable period. The opening up of the Outsider Group, Maple Bay, is proceeding satisfactorily and ore shipments from this property to the Anyox plant are expected to commence at an early date.

Stewart — Some splendid ore is reported to have been uncovered recently in the workings of the Indian Mines Ltd., Salmon River, Portland Canal. It was struck in the No. 1 tunnel of the mine which now is in a distance of 810 feet. The published description of the find follows: " On striking the ore two drifts were driven on it 18 feet apart, with ore on both walls, leaving a pillar of ore between. In one of these drifts the ore occurs in sulphide form in heavily mineralized quarts, several feet of which being sampled gave returns of 0.68 oz. gold, 210 oz. silver, with no lead. Two feet of solid ore which occurs in the other drift gave a return of 2.72 oz. gold, 7.9 oz. silver and 7.4 per cent lead. Some of the prettiest specimens of native and wire silver ever taken from depth in the camp were brought to Stewart from these workings. " Development is proceeding and diamond-drilling also is under way, the latter, according to statements made by those in charge, being satisfactory in its results.

The Dunwell Mines Ltd., Portland Canal, has been very active in development since the ore-body was crosscut in No. 2 Tunnel. The drift each way is said to be following the foot-wall of the vein, the two faces being now over 700 feet apart. The ore is enriched with secondary minerals. No. 3 Tunnel is being driven at the rate of five feet a day and the ore-body will be struck, it is figured, at a depth of 170 feet below No. 2 Tunnel. The tunnel now is in about 75 feet. The plant consist of a compressor and two machine drills. The Company, it is reported, has withdrawn its stock from the market although some private sales have been made at $1.50 a share. The Dunwell is capitalized at $350,000.

Mining Dividends — The Premier Gold Mining Co., The Howe Sound Mine of the Britannia Mining & Smelting Co., and the Silversmith Mine are the three British Columbia mining enterprises at present on a dividend paying basis. They have distributed $1,800,000 this year. The Premier's dividend for the third quarter of the year brings its total dividends to $4,450,000. The Howe Sound Mine for the first time in several years paid a dividend in the second quarter of the present year, $199,208 being distributed. For the third quarter the same dividend has been declared. The Silversmith has paid $100,000 in dividends this year. For the first quarter it paid $25,000; for the second $50,000; and for the third $25,000. In 1922 it paid $100,000 and in 1921, $25,000, making a total of $225,000.

Electrolytic Iron Experiments — W. B. Timm, chief of the division of ore dressing and metallurgy of the Dominion Mines Department, states that the Dominion Government is constructing a laboratory at Ottawa for investigating the possibility of producing commer

electrolytic iron made from the iron pyrites con-ned in ore waste. Experiments along this line e started several years ago by metallurgists of Consolidated Mining & Smelting Co. at Trail. these tests the experiments were confined to the ores the Sullivan Mine. It is proposed to experiment at awa with the waste of the various operating mines Canada.

Address by Minister of Mines — Problems of Min- on Vancouver Island, was a subject of recent lress to the Kiwanians of Victoria by Hon. Wm. an, Minister of Mines. He referred to placer min- at Leach River, Sooke District, in the early days t to the first developments in metalliferous mining. Sloan was optimistic as to the future of the latter m of industry, mentioning specially in this connec- n the opening up of a large deposits at Jordan er, on the West Coast, the activity on the minerals ims known as the " Old Sport ", Quatsino, and the mising character of prospects such as the Big In- ior, Great Central Lake, and other properties in different mineralized districts of the island. All t was wanted was a healthy copper market to bring se and other prospects into production and some uld become substantial shippers.

Mr. Sloan spoke of the problem of dual control in E. & N. Land Belt, an area comprising about one- arter of the Island. He said that negotiations were progress between the Railway Company and the partment of Mines having in view the administra- n of the base minerals as well as the precious mine- s solely by the Province. These had not yet been ccessful but he was hopeful that a satisfactory solu- n of the problem would be reached.

The greater part of the address was directed to the estion of fuel oil importations to British Columbia d the effect on the coal mining industry. Quoting m recently compiled statistics Mr. Sloan showed that production of fuel oil on the Pacific coast had jump- from eight million barrels a month in late years to enty-five million barrels in July of this year. The ospect was that it would reach the thirty million rrels a month mark during the closing months of e year. All this fuel had to be absorbed by the mar- t. It was being imported to this province in eater quantities than ever before. Coal produced ally was being displaced in the domestic market d the great basic industry of British Columbia was ing threatened. This was a problem, Mr. Sloan as- rted, that it would be well for people to understand. was one that called for sympathetic action on the rt of those in authority as well as by the fuel nsuming public, who desire to see local resour s developed and local industry encouraged.

Mr. Sloan made it clear that, while there were oblems demanding attention, the outlook was bright. stable copper market and an effective check to the rious competition with which the industry is faced ere all that is needed to improve conditions. Given is, nothing could hold back the advance of mining the Island.

RECONSTRUCTION IN JAPAN

It is estimated in Tokio that the rebuilding of the evastated area of Japan will last from five to seven ears and that it will induce a period of prosperity roughout the Japanese Empire, due to the material sed and the employment provided.

NOVA SCOTIA

Miners Ask Increased Wages. — The officers of district No. 26, United Mine Workers of America, notified the British Empire Steel Corporation that in the new agreement shortly to be discussed, they will request the restoration of the 1921 wage rates. The agreement under which they are now working expires on January 15th, but there is a desire to have the matter brought up early and discussed so that an agreement can be entered into without any stoppage of work.

Coal Heaps Almost Gone. — Nearly all coal from the heaps made last winter has been filled away. It is very late in the season to have coal heaps at the collieries, but this was due largely to the strike. There is at present considerable idle time at the collieries, and two of the smaller mines have been closed down, the workmen being distributed among the other collieries.

British Coal in Newfoundland. — A large amount of lumbering has been done in Newfoundland this year and great quantities of pit props were shipped to Great Britain. Coal was brought out as return cargoes and cut into the trade of the B. E. S. Co. Without the advantage of a cheap return rate, the British coal could not have gained much of the market.

Slack Time at Wabana. — The Wabana ore mines may be forced to reduce their output further by laying off 200 men in addition to those already let go. During the whole of this year the Company has struggled to give employment to the largest number of men possible. In addition to ore shipments, 1,000,000 tons are in the stock piles at Wabana, and Sydney is fully stocked for the winter, having 500,000 tons in the bins. Over 700 men will be kept employed during the winter for development and further output. With improved conditions prevailing in Europe, the ore trade may take a sudden change for the better and the Company intends to keep the mines fully developed.

Repairs to Furnaces. — A number of the furnaces at the Sydney steel works are down for repairs. As sufficient stock had accumulated, there is no diminution of the output of manufactured products. Sixty coke-ovens are being heated and will be ready to produce blast-furnace coke by the middle of the month. This, with the 120 ovens now in operation, is strong evidence that the Sydney steel plant is having a fair share of the present prosperity of the steel trade. The new ovens now being heated for the first time were built in 1921.

The Wages Question. — The Dominion collieries have had less broken time in the latter part of October after the coal heaps were filled away. There is much speculation as to the winter's trade, but if the miners are at all reasonable there is little doubt that 1924 will see at least an increase of one million tons over this year. With a wage agreement to be negotiated soon, there is considerable apprehension of labor agitation. This should not be. The wages made by the contract miners are high and rank above those of other classes doing work of a hazardous nature. Any adjustment that might be made (and it is doubtful under present conditions if any can be made) should have for its object the levelling up of the lower paid classes of labor. With steady employment, conditions at the collieries are considered by the miners themselves as very fair.

First Aid Certificates. — The examination of candidates for the different grades of First Aid certificates held some time ago shows that in the Glace Bay district thirty-five of the number up for examination passed. Of these, James McMahon, General Superintendent of Rescue Stations, won the highest certificate, — the Medallion and Label; thirteen won the Medallion; eight the Voucher 2nd Certificate and 13 the First Aid Certificate. The examinations were conducted by Dr. Bruce of Sydney, assisted by G. A. Rowlings, President of the St. John's Ambulance Association.

First Aid Classes. — Night classes in first aid to the injured are conducted each winter by the Dominion Coal Company, and considering the labor agitations of the past two or three years and the exceptional severity of the weather last winter, the progress made has been encouraging. It is understood that an effort is to be made this winter to enlist the support of the United Mine Workers as a body. The locals will be visited and the matter laid before the workmen with a view to enlarging the classes. Supt. Hector McDonald, who is in charge of the work, is an enthusiast and believes that a personal appeal will be all that is necessary to draw the interest of the miners to this important duty.

A peculiarity of Nova Scotia collieries compared with those of Great Britain may be pointed out. Whereas the miners of Britain complain of the lack of interest taken in first aid work by the mine operators, the mine workers of Nova Scotia fail to attend classes in large numbers. Probably this was in the past due largely to the propaganda of the labor leaders against the Coal Company; but when the Company provides the place, the books and all other necessary material for instruction, and the colliery doctors give freely of their time, the response should be generous, as the work is one wholly in the miners' interests and that of their families.

Coal Production.—The Dominion collieries produced 294,596 tons of coal in October, which brings the total for the year to date up to 2,867,000 tons, which is 625,000 tons ahead of last year.

McLachlan Sentenced. — Following his conviction on a charge of seditious libel recently, J. B. McLachlan was sentenced last week to two years' imprisonment, the maximum penalty, by the judge.

New Colliery Site being Tested. — Drillers are at work testing the proposed site of the new colliery at Lingan. A railway spur is under construction and the shaft will be begun as soon as the best location has been determined. The estimated output of the new colliery is 2,000 tons a day, which will rank with the largest.

GRANBY EXPLORATIONS IN 1923

The little weekly of the Anyox Community League, *The Granby News,* publishes in a recent issue the following announcement:

With the snow about to fly, the exploration season of 1923 is practically finished, at least in so far as the Granby Company is concerned; and while there are one or two matters not yet definitely decided upon, the General Manager, Mr. H. S. Munro, announces that the Sultana Group, in the Hazelton District, after considerable prospecting with the diamond drill, has been dropped, likewise the property on the Extal River, belonging to the Dunsmuir Estate. The Sunshine group, in the Portland Canal section, has also been abandoned. A further bond, covering a period of a year, has been arranged in connection with the George property in the same section. Owing to the present condition of the copper market, which shows no sign of improvement for the future, Copper Mountain will be shut down for the present, and those who went from Anyox to that operation will return here until such time as copper conditions are more favorable. At Maple Bay everything is being rapidly put in shape for shipping, as the ore will soon be moving to Anyox from this point. Diamond drilling on the Eagle Claims, adjoining the Outsider group, gives sufficient assurance that a big shipping mine will be developed, and all the ground of any possible worth in this vicinity has been bonded by the Granby Company.

A NEW SWEDISH MOTOR FUEL

Recent experiments carried out in Sweden are said to have demonstrated the commercial value of a motor spirit called "bentyl," which is composed of sulphite spirit distilled from the sulphite lye of the wood pulp mills mixed with 20 to 25 per cent benzol (motor). As there are now 22 sulphite distilleries in Sweden with an annual output of about 20,000,000 liters of 100 per cent alcohol from lye, the new motor fuel may prove to be a serious competitor of imported gasoline. Imports of gasoline into Sweden during 1922 totaled 56,783,000 kilos (approximately 20,000,000 gallons), according to official statistics, of which 28,273,759 kilos came from the United States.—**Commerce Reports.**

INDEX TO MINE AND MILL SUPPLIES

Addresses of advertisers whose names appear in the following classified index, may be found upon reference to their advertisements. An alphabetical index to advertisers will be found on the page facing the inside back cover. The following regulations apply to all advertisers: — One-eighth page, every issue, three headings, one-quarter page, every issue, six headings; one-half page, every issue, twelve headings; full page, every issue, twenty-four headings. Buyers who are unable to find in the classification here given such machinery or supplies as they desire are invited to write Service Dept., Canadian Mining Journal, Gardenvale, Que., who can, in all probability, refer them to proper sources.

Harnessing Horsepower

ECONOMY is your chief consideration in harnessing horsepower for mining operations. In lifting or pulling light loads of a thousand to fifteen hundred pounds, Model 3 3-hp. Leadville column hoist or Model 5 5 1-2-hp. Super Leadville will solve the problem, while for heavier loads in slushing or scraper mining the 10-hp. double-drum Model 300 Turbro Waughoist is an ideal machine.

LEADVILLE column hoist (manufactured by The William A. Box Iron Works Company, of Denver, Colorado), have stood the test of long years of successful operation in mine and quarry and are now exclusively sold by this Company in conjunction with its Waughoist. Booklets descriptive of these machines will be sent upon request.

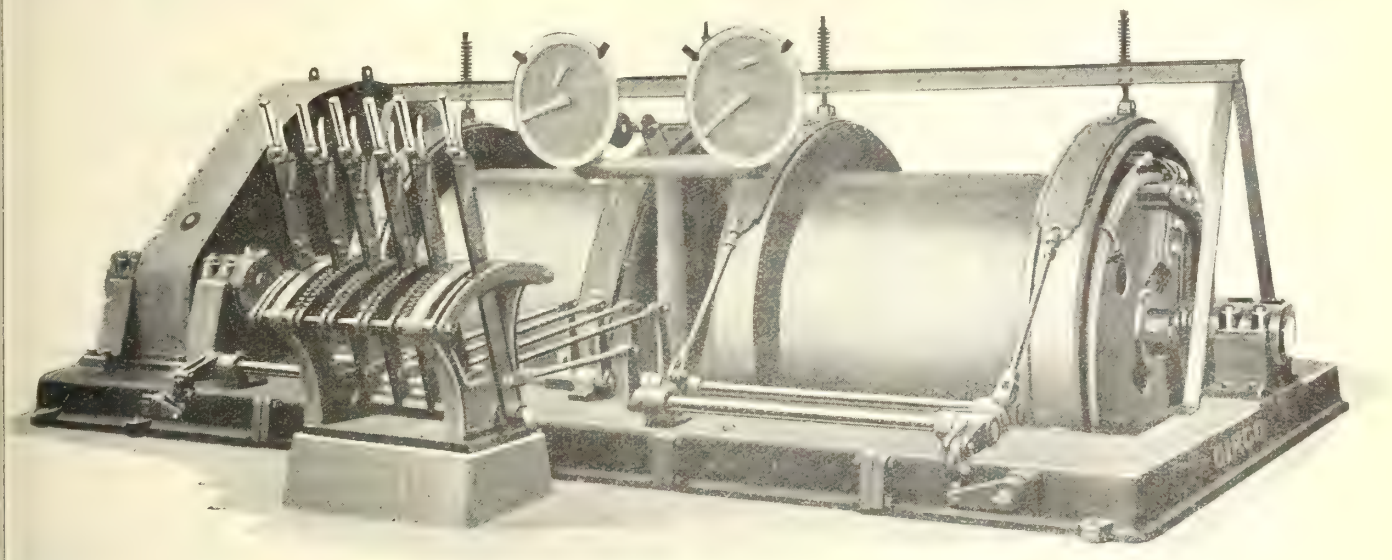
"CIRCO" HOISTS



To Meet Your Specific Requirements

THERE are many requirements which your hoist must meet in order to give best possible service from the standpoints of large output, convenience, safety, reliability and low operating cost.

Sometimes these are sufficiently unusual to necessitate the use of specially designed equipment, but in the mapority of cases one of our many standard hoists will do the work with little or no change.

And up to a certain point all CIRCO Hoists are built standard, so that even when special units are required they can be furnished with but moderate special manufacturing changes.

We are always glad to study conditions thoroughly and then recommend the size, type and equipment of the hoist best adapted to meet them safely and economically.

Many of the foremost mines and collieries in Canada have made use of this service as it results in the installation of a machine combining moderate first cost, convenient control, low operating and maintenance charges, to a degree which reflects favorably upon the operation of the entire property.

Ontario's Minerals

PROVINCE OF ONTARIO

Hon. CHARLES. McCREA, Minister. DEPARTMENT OF MINES *Thos. W. Gibson*

Mineral Areas

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favourable for the occurrence of minerals 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver veins of Cobalt, Gowganda and South Lorrain occur in these rocks; so also do the far-famed nickel copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

Economic Minerals

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario: — actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluorspar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, Portland cement, brick and tile, meet every demand.

Mineral Production

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1922 to be worth $62,202,169, of which the metallic production was $38,190,711.

The following figures show the growth of Ontario's mineral industry by five-year periods since 1891 when a Bureau of Mines was first established.

Year.	Value.	Year.	Value.
1891	$4,705,672	1911	$41,976,797
1896	5,235,003	1916	65,303,822
1901	11,831,086	1918 (Maximum war output)	80,308,972
1906	22,388,383	1921	48,128,387

Dividends and bonuses paid to the end of 1922 amounted to $28,096,699 for gold mining companies, and $86,238,185 for silver mining companies or a total of $114,334,884.

Mining Regulations

A miner's license costs $5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of $2.50 or $3.00 per acre, depending on location in unsurveyed or surveyed territory.

Assay Office

The Provincial Assays Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

Publications

For list of publications, illustrated reports, geological maps and mining laws, apply to

Thos. W. Gibson,
Deputy Minister of Mines,
TORONTO, CANADA

BRITISH COLUMBIA

The Mineral Province of Western Canada

as produced Minerals valued as follows: Placer Gold, $76,542,203; Lode Gold, $109,647,661; Silver, $59,-4,266; Lead, $51,810,891; Copper, $170,723,242; Zinc, $24,625,853; Coal and Coke, $238,289,565; Building one, Brick Cement, etc., $36,605,942; Miscellaneous Minerals, $1,358,839; Making its mineral production the end of 1922 show an

Aggregate Value of $769,418,462

The substantial progress of the Mining Industry of this Province is strikingly exhibited in the following gures, which show the value of production for successive five-year periods: For all years to 1895, inusive $94,547,241; for five years, 1896-1900, $57,607,967; for five years, 1901-1905, $96,509,968; for five ears, 1906-1910, $125,534,474; for five years, 1911-1915, $142,072,603; for 5 years, 1915-1920, $189,922,725, 921, $28,066,641; for the year 1922, $35,158,843.

Production During last ten years, $339,280,940

Lode-mining has only been in progress for about twenty-five years, and not 20 per cent. of the Provnce has been even prospected; 300,000 square miles of unexplored mineral bearing land are open for prosecting.

The Mining Laws of this Province are more liberal and the fees lower than those of any other Province n the Dominion, or any Colony in the British Empire

Mineral locations are granted to discoverers for nominal fees.

bsolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown rants.

Full information, together with Mining Reports and Maps, may be obtained gratis by addressing.

VICTORIA, British Columbia

THE HON. THE MINISTER OF MINES

PROVINCE OF QUEBEC

MINES BRANCH

Department of Colonization, Mines and Fisheries

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, etc.

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

MINER'S CERTIFICATES. First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. The price of this certificate is $10 and is valid until the first of January following. This certificate gives the right to prospect on public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres

WORKING CONDITIONS. During the first six months following the staking of the claim, work on it must be performed to the extent of at least twenty-five days of eight hours.

SIX MONTHS AFTER STAKING. At the expiration of six months from the date of the staking, the prospector, to retain his rights, must take out a mining license.

MINING LICENSE. The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cents an acre per year, and a fee of $10.00 on issue. It is valid for one year and is renewable on the same terms, on producing an affidavit that during the year work has been performed to the extent of at least twenty-five days' labour on each forty acres.

MINING CONCESSION. Notwithstanding the above, a mining concession may be acquired at any time at the rate of $5 an acre for SUPERIOR METALS, and $3 an acre for INFERIOR MINERALS

The attention of prospectors is especially called to the territory in the North-Western part of the Province of Quebec north of the height of land, where important mineralized belts are known to exist.

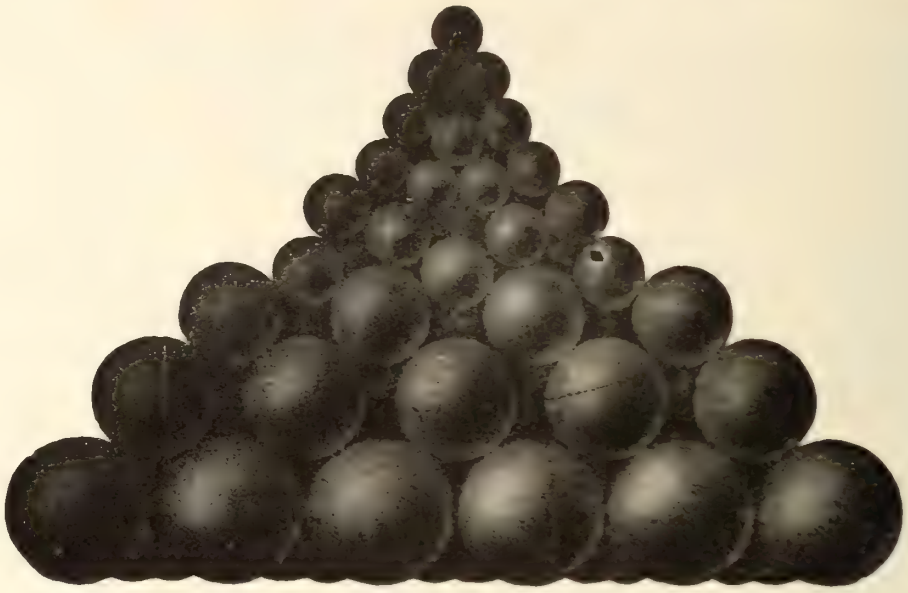
PROVINCIAL LABORATORY. Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY, 228 ST. DENIS STREET, Montreal, for the determination, assays and analyses of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensure results of undoubted integrity and reliability.

The bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of the Province, on application addressed to

HONORABLE J. E. PERRAULT,

MINISTER OF COLONIZATION, MINES AND FISHERIES, QUEBEC

Decrease your grinding costs.



USE HISCO BALLS

"If quality counts use 'Hisco' Products" *Hisco Balls* are noted for superior quality. They are in use in the largest ore and cement mills from Halifax to Vancouver. Forged from Electric Furnace chrome steel, absolutely the best ball on the market.

Sizes 3, 4, 5 and 6 inch carried in stock.
Special sizes from 6 inch up made to order.

A Bank That Is Always Near

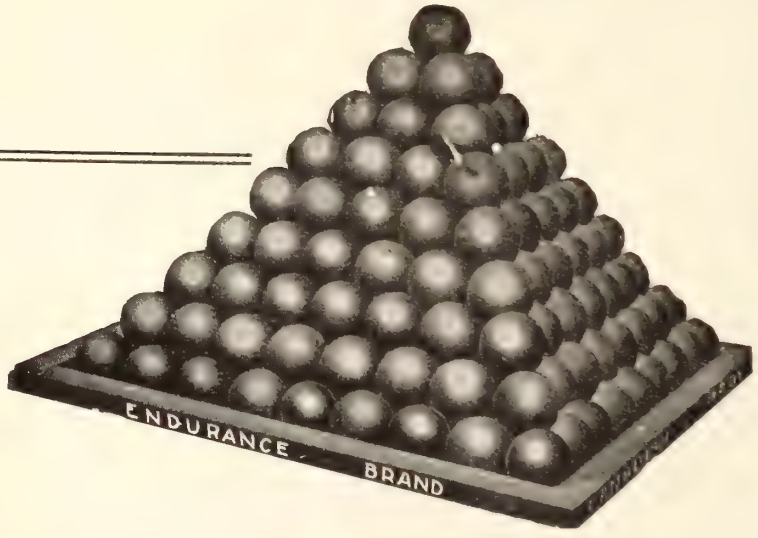
The mining engineer — moving as he does from place to place — must needs utilize a bank which has branches conveniently located in mining centres.

The Imperial Bank, with 192 branches throughout Canada and with special concentration in mining districts, offers distinct advantages to those engaged in the mining industry. Patrons of this Bank are never far from their bank accounts, no matter to what part of the Dominion they may go.

Why not ensure adequate banking facilities by depositing your funds with this Bank?

IMPERIAL BANK OF CANADA

Peleg Howland, President. A. E. Phipps, General Manager



Depend upon ENDURANCE Forged Steel BALLS

You can avoid needless annoyance and unnecessary cost by ordering Endurance Grinding Balls.

They will furnish the economical service that will materially reduce your grinding costs.

Write for prices and particulars and ask about the Cam Shafts, Shoes and Dies we make. They are equally reliable.

WANTED — MORE UNITY IN OUR MINING INDUSTRY

The mining industry of Canada is coming more and more under the scrutiny of visitors from Great Britain and foreign countries who are interested in its development and exploitation, its products and its personnel. Our mining industry, like our country itself, has assumed national importance, and should be directed from a national point of view. We are now fully conscious that Canada has reached nationhood. Is her mining industry a national unit before the world? We fear it is not.

So far as we are aware, the only truly national representative of Canada's mineral industry (excluding ourselves!) is the Canadian Institute of Mining and Metallurgy. The technical personnel of the industry has effected a nation-wide organization and its influence extends from coast to coast. It is this national institution that provides the avenue of approach to Mr. Hugh F. Marriott on his mission from Great Britain. He is to visit each of the Institute's branches from Pacific to Atlantic, and no doubt will gain an impression of Canadian mining engineers united in a common cause, whatever the divergence of opinion may be on the various questions to be discussed.

To outsiders who approach our mining industry by any road other than the Institute, it will present, we fear, a dis-united and heterogeneous appearance. Apart from the prairie provinces, whose mineral resources still continue to be administered by the Federal government, the provincial governments formulate and administer the mining laws and policies. Though there is some semblance of similarity in the fact that they all attempt to conform to the ideals of democratic government and of British justice, there is little else that is common to them. The mineral resources of the eight provinces (for "The Island" has no mining industry as yet) are administered under laws more divergent than those of Canada and some foreign countries. There is at present no serious attempt to shape policies according to a common standard, acceptable to all. There is plenty of common ground on which the federal government and those of the provinces stand; but up to the present our political administrators have failed to consult one another with a view to marking it out.

It appears to us that the present is an opportune time to make a move towards unity. Those responsible to the public for our mineral resources from coast to coast might well confer on this subject. Of all our basic industries, mining is at present the most active and the most prosperous, and its growth during the next few years promises to bring it to a position of much greater relative importance to the country. The policies and laws under which the mineral resources are administered are among the most important factors affecting their development, particularly on account of their influence on investors. The heterogeneous character of the present sectional laws is bound to confuse the investor, as well as others from outside who have not been brought up to take for granted their variety and their complexity. In many cases this diversity is more the result of accident than of design. In other cases a compromise between divergent views will be much better than either extreme. In any case, the matter is worth close consideration by the combined forces of the federal and provincial Departments of Mines.

We make this suggestion knowing that it is likewise in the minds of a number of the leaders of our mining industry, and confident that prompt action will ensue should the idea commend itself to our public administrators.

MR. WOLVIN ANNOUNCES PENSION PLAN

Mr. R. M. Wolvin, President of British Empire Steel Corporation, announced last week the inauguration of a pension fund, details of which are recorded today by our Nova Scotia correspondent. In announcing the scheme, Mr. Wolvin said he had had it in mind ever since he became president of the new corporation in 1920. In our opinion it marks definitely a breadth of outlook and a soundness of principle that is well worthy of this, one of the greatest of Canadian industrial corporations.

A notable feature of the new pension scheme is that its cost is borne entirely by the Corporation. While a coöperative pension fund has certain advantages, it presupposes a spirit of thrift that often is found not to exist generally among the workmen.. In the present case the antagonism between workmen and employers exemplified in the recent strikes makes the scheme as formulated even more advisable. Mr. Wolvin and his directors have chosen wisely a course that should go a long way towards winning over the workers of Cape Breton to the loyal service of their employers.

It is mooted in Sydney also that the Corporation shortly will offer to its employees an opportunity to buy preferred stock under conditions advantageous to themselves. This plan has had such excellent results for both workmen and employers in the case of a number of substantial companies in this country, as well as abroad, that its adoption in Sydney might well prove of decided advantage to all concerned.

SURTAX ON GOLD MINING PROPOSED

The Minister of Finance at Ottawa has proposed that a surtax be levied on gold mines in Canada. This is the tenor of his recent announcement that the embargo on the export of Canadian gold is to continue, but that the premium obtainable by selling this gold in the United States shall be retained by the government instead of being turned over to the mining companies. Mr. Fielding upholds his stand by saying that the mining companies are prosperous and can well afford to contribute this additional sum towards balancing the budget. . The estimated amount of the surtax this year is $500,000. We doubt if Mr. Fielding has gauged accurately the cost of raising this half million dollars.. In our estimation it is likely to cost the country much more than the amount raised.

Hon. Charles McCrea, Minister of Mines for Ontario, has pointed out repeatedly and forcefully the fact that the security of capital invested in the mining industry in Canada is one of the chief attractions we can offer investors, particularly foreign investors. Stable laws, liberal regulations and consistent policies are an asset of no mean dimensions to a young country like ours, necessarily dependent in part upon the stored-up energy represented by British and foreign capital for the rapid development of our resources. Ministers of he Crown and other responsible public servants in other provinces have voiced the same sentiment. All realize the value of security to investors, and each has adopted means of ensuring it.

Now Mr. Fielding proposes an impost that will assuredly tend to destroy the feeling of confidence and security that others have been at such pains to build up. The tax is not heavy; but what will be the next move in the same direction? This will set a precedent for the federal taxation of a provincial resource; how much further can the idea be developed to help fill the empty treasury at Ottawa? The youthful gold mining industry is prosperous and the established mines are yielding handsome revenues to their owners and to the provinces; are there other melons as well from which the Dominion can cut a slice?

We should bear it in mind constantly that, though we have now a number of well-established gold mines, all evidence points to the fact that there will be many more of them during the succeeding years. How large our gold mining industry will be eventually, we can only guess. It is now only an "infant industry", and in its estate of manhood it may be a source of national income that will make Mr. Fielding's proposed $500,000 tax look small. Its growth will depend largely upon the capital fed to it. It will be a dangerous experiment to trifle with this infant's nourishment in such a way as may retard and stunt its growth.

Mr. Fielding's proposed impost on the gold mining industry is dangerous, as it infringes upon principle that should be held inviolate. It is inexpedient, because the amount of money it is proposed to raise for the federal treasury by this means is not commensurate with the risk of injury to the industry it involves.

NEW ROAD FOR QUEBEC GOLD-FIELD

Hon. J. E. Perrault, Minister of Mines at Quebec has authorized the immediate construction of a winter road into the gold district of northwestern Quebec from the south, and has promised that this winter road shall be made into a summer road next season. As the minimum cost as estimated at present by the Minister is $200,000, he and his colleagues obviously intend to provide a permanent and well built road for the use of the prospectors, miners and settlers who will develop the combined mineral and agricultural resources of this important area.

The new road will commence at Angliers, the present northern terminus of the Kipawa-Des Quinze branch of the Canadian Pacific Railway at the Quinze storage dam, and will run northward for a distance of forty miles on a location made recently by Mr. Normandeau of the engineering staff at Quebec, to Boischatel township. Its course will be through the fine clay land west of Des Quinze and Barriere lakes and east of Lake Opasatika, crossing mid-way the Lonely river, which joins the last two lakes. At a suitable point in Boischatel township a branch road will be constructed westward to Lake Fortune, and another eastward into Rouyn township, with the Noranda camp as its present terminus. It is expected the winter road will be ready for use by the end of December.

As mentioned before in these pages, the gold belt of northwestern Quebec stretches along the southern edge of the Great Clay Belt for one hundred miles, and a lobe of the belt extends southward to Ville Marie. The new road will run through the centre of this lobe of agricultural land for a distance of forty miles, and its projected branches in Boischatel and Rouyn townships will serve a large area of excellent clay land as well as the prospective mines. The route chosen is also that which an extension of the railway from Angliers will naturally follow, so that its construction in the future (possibly in the near future) will be preceded to some extent by the settlement upon which its ultimate solvency will depend. If the

present gold prospects at Noranda and Lake Fortune should turn into mines (and there is every reason to believe they will), then the cost of the new road, and indeed of the railway as well, will be insignificant compared with the bullion that will be shipped over them, and settlement round the mines will proceed at a rapid pace.

We have also noticed before in these columns the fact that, once convinced of the wisdom and expediency of a course of action, the political administrators at Quebec are known for swift, decisive and thorough practical measures. Mr. Perrault's decision to build this road illustrates well this point. It is less than six months since the two finds were made upon which our hopes for the immediate future of the district are centred. Their development during the coming winter warrants the provision of a road, and Mr. Perrault and his associates have decided promptly to provide it. It is more than likely that the winter's work will demonstrate the necessity of a summer road, and adequate provision has been made for it. Meantime, the amounts to be expended are amply covered by the benefit that will be derived from the road as an agency of colonization.

The *Canadian Mining Journal* wishes to congratulate Mr. Perrault and his colleagues upon their well-judged and timely decision. It will provide an invaluable aid to those whose time, energies and money are being used without stint to prove the gold-field of northwestern Qeubec.

THE QUINZE AND THE ONTARIO-QUEBEC MINERAL BELT

At present there is plenty of power for the mines and mills of Northern Ontario. If the coming winter season should prove unfavourable, there may be a recurrence of power shortage during the winter, but it is not at all likely it will be so serious as that of last winter. Before the next normal season of low water, in the winter of 1924-25, the two new power plants on the Abitibi River and on the Quinze River will be ready to augment the supply of electrical energy. The Hollinger will absorb the output of the plant on the Abitibi River, and, we are confident, there will be, by that time, a large demand for the Quinze power. To gauge this demand we must take a peep into the future of the area within reach of Quinze River.

First of all, it is well to bear in mind the fact that Sudbury is as close to the Quinze River as is Timmins. It has been decided already to construct a power line from the Quinze to Porcupine; a line could be constructed with equal facility to the great nickel camp. A circle of 110 miles radius, with centre at the Quinze, touches Timmins, strikes through the centre of the nickel camp, and includes by far the larger part of Ontario's metal mines, present and prospective. This circle includes as well the whole of the Quebec gold belt, the western end of which is forty miles from the new power plant.

Within this area, which is now and promises to be for many years to come the most important metal mining district in Canada, the water powers adjacent to developed mines are now virtually all in use. Apart from undeveloped powers on the Ottawa River below Lake Temiskaming and some small powers on the Abitibi River, the Quinze is the only substantial source of supply for the mines of the future. Fortunately the amount of power available in the fifteen falls and rapids that give the river its name is very large, its drainage basin extends eastward for over one hundred miles and includes 9,500 square miles, and there are excellent opportunities for regulating the flow of water by storage dams.

Though the present demand for power at the mines does not reach the total of that under development, it appears as if it would reach that total within a few years, and within a short term of years will much exceed it. Consider the near-mines first. Vipond's future is assured, and it is possible it will develop into a fourth to be added to the "big three" of Porcupine. Goldale and Newray are only one stage removed from being mines, and the substantial sums now appropriated for their further development by the experienced engineers in charge is a sufficient indication of the good chances for success. The work now in progress on various other properties in the Porcupine camp is more than likely to disclose some more workable gold deposits.

The productive area at Kirkland Lake will be extended materially in the near future, unless the judgment of New York and London investors who have taken up properties at substantial prices during the past year is astray. There is no large surplus of power available in the camp, and the Quinze will be its chief recourse for an augmented supply.

Far from declining in interest, the silver areas of which Cobalt is the centre are attracting more attention every day, and the expenditure on exploration thus stimulated will probably result in the establishment of a number of new and important mines. A substantial beginning has been made at the Keeley and the Frontier, and other likely-looking localities in South Lorrain are now being investigated. Veins in a similar geological location in the Gillies Limit to the northwest are being explored seriously for the first time. Further underground prospecting along the lower contact of the diabase sill at the Beaver and Temiskaming mines is being well rewarded. On the Columbus and Ophir claims, just to the south and southwest of these, promising showings in the Keewatin greenstone have never yet been followed down to the underlying diabase; no doubt the present wave

of interest in silver properties will result in this being done. Certain parts of the Gowganda area, in the vicinity of the present producers, have never yet received the attention they deserve; probably they too will now be explored. Should the course of well-directed exploration in these various silver areas be attended with even an average reward, the new mines will augment materially the total requirement for power, which depends ultimately upon the Quinze.

Prospective mines in Quebec's gold belt will be almost entirely dependent upon the Quinze for their power. What their total requirement will be, only time will tell, but there are some mining men and geologists, known to us for their solid conservatism and long vision, who have ventured to predict that, before many years have passed, the gold mines along this hundred miles will require the development of another and still another of the water-powers of the Quinze.

Northeastern Ontario and northwestern Quebec seem destined to become one of the world's great centres of metal production. Already this area is pre-eminent for its nickel and cobalt, and famous for its silver and gold. The Quinze will be the centre of its power supply. It is fortunate that nature has provided in so convenient a locality such a vast potential source of electrical power.

COAL IN THE MARITIME PROVINCES*

By John McLeish**

Less than one per cent of Canada's total coal resources are found in her eastern coal fields in the provinces of Nova Scotia and New Brunswick, all of the rest being west of Winnipeg. Nevertheless the collieries of Cape Breton were among the first worked on the American continent and during 1922 the eastern fields produced 39 per cent of the total Canadian output. Mining operations are known to have been in progress since 1785 and indeed many of the difficulties now encountered in this field are due to the early attempts at mining when the main object was an immediate output of fuel at lowest possible cost and little consideration was given to the future possibilities of undersea mining at long distances from shore shafts.

The coal, which is bituminous in character and of varying quality, is mined in five areas, or fields, usually referred to as the Sydney and Inverness fields in Cape Breton, the Pictou and Cumberland fields in Nova Scotia proper, and the Minto field in New Brunswick. The Sydney field is the most extensive and is credited with about 78 per cent of the total available coal in the two eastern provinces. The Cumberland and Pictou fields possess a little less than 10 and 9 per cent respectively of the total; the Inverness field about 2½ per cent; and the New Brunswick field about 1½ per cent.

In 1913, the two provinces produced a total of 8,050,000 short tons and in 1922 only 5,850,000 tons. The relative amounts produced from the several fields last year were: Sydney field 70 per cent; Cumberland 11.8 per cent; Pictou 9.7 per cent; Inverness 3.4 per cent and Minto 4.9 per cent. The output is used largely for locomotive fuel and for bunkering ships. It is used by industrial power plants in Eastern Canada and for the manufacture of coke to supply the iron and steel furnaces at Sydney. It is also used to a large extent as a domestic fuel throughout the Maritime Provinces. For domestic use the output of particular mines and selected seams is employed, but even at that many consumers in the cities of Halifax and St. John and other points prefer to pay a much higher price for Pennsylvania, or Welsh anthracite. Much of the Nova Scotia coal is high in sulphur and for the manufacture of metallurgical coke a careful selection of the coal is necessary. The coal so used is further washed to reduce its ash and sulphur content. In 1914 over 2,600,000 tons of Nova Scotia coal were marketed in the province of Quebec. During the war this market was almost entirely lost but by 1922 had been regained to the extent of about 50 per cent.

Production during the first six months of 192 showed a decided improvement over the corresponding period of 1922 with an increased production of over a million tons and with largely increased shipments to the Montreal market contracted for.

It is estimated that the strike during July caused a loss in ouput of about 400,000 tons. It also resulted in a loss of some of the sales that had been made in the Montreal market. Within two weeks of the resumption of mining, however, the daily output again reached a high level.

Practically every colliery is working at maximum output consistent with the available labour for work at actual mining. A persistent shortage in the number of miners has been increased through considerable numbers joining the ranks of the harvesters going to Western Canada. Yet despite these drawbacks if there are no further serious interruptions to output the 192 production may exceed that of any of the past six years.

At the present time large expenditures are being made on permanent improvements that will contribute materially to a better and safer production of coal.

With labour conditions on a more satisfactory basis and rates of compensation so adjusted as to attract and retain the native miner, our eastern coal fields will be placed on a better basis to take care of wider markets. The extent to which these wider markets can be obtained in central Canada will depend on ability to compete in quality and price with the enormous producing capacity of United States bituminous mines.

* From "Natural Resources," Ottawa.
** Director, Mines Branch, Ottawa.

CANADIAN ENTERPRISE IN PERU

The field investigations in Peru of Canadian petroleum geologists in the employ of the Imperial Oil Company have resulted, within a decade, in a marvellously productive oil field being found and exploited. A large part of the white community at Talara ano Negritos, the chief of the little desert towns established at the refinery and the oil-fields, is Canadian, and the constant movement to and fro necessitated by the tropical climate of this part of Peru has made a considerable number of Canadians familiar with this part of the southern hemisphere. The Imperial Oil Company maintains its own tanker fleet, and so a notable part of Canada's petroleum supply, though derived from a foreign land, is completely under Canadian direction.

Natural Gas and Petroleum Resources of Western Canada

Helium—Its Occurrence, Recovery and Use

By NEWTON W. EMMENS

The success attending the flight of the United States gid airship ZR-1 from New York to St. Louis and eturn is an epoch-making event in aerial navigation ith heavier than air machines. It is the first time n history that an airship has used the gas helium as s lifting force, instead of the gas hydrogen. For hose unfamiliar with the subject the outstanding im- ortance of the replacement of hydrogen by helium or inflating airships can be better realized when it is nown that helium is non-inflammable, retains its fting power for a greater length of time owing to ts diffusing and consequent waste through fabrics eing only one half that of hydrogen, and yet has 92 per cent. of the buoyancy of this latter gas.. This neans that all danger of explosion or burning of an irship filled with helium is removed, and its cruising adius is increased because the helium retains its lift- ng power for a longer time.

Canadian Helium Reserved to the Crown

The petroleum and natural gas industry is directly nterested in this subject because natural gas is the nly known source of helium in quantities sufficient o make its separation and recovery practicable, and he United States and Canada are the only countries having natural gas sufficiently high in helium to make its extraction on a commercial scale possible, so far as our present knowledge extends.

The governments of the great powers are fully alive to the value of helium for military and naval purposes, as is shown by the vast sums spent upon developing a process for its recovery and in investigating every possible source; and our own country has not only played an important part in these investigations, but reserves to the Crown any and all helium contained in natural gas obtained from any Crown lands under lease, with the right to erect plants for its recovery. A clause to this effect is inserted in the petroleum and natural gas leases issued by the Department of the Interior,—a wise provision, because the cost of the requisite plant is very high and the market for the product extremely limited, being confined entirely to aerial navigation with heavier than air machines. In time of war, however, the possession of a large supply of helium will be a matter of vital importance, and will give the country possessing it an advantage almost impossible to overcome.

Helium in the Sun, and in Uraninite

The element helium was first discovered by J. N. Lockyer in the year 1868 during an eclipse of the sun, when he was making a study of the chromosphere (the layer of incandescent gas surrounding the sun) with the aid of a spectroscope. While Lockyer recognized many of the terrestrial elements in the solar chromosphere, he noted and called attention to a brilliant yellow line in the spectrum which, while apparently associated with the yellow lines of sodium (known as the "D" lines), did not exactly correspond with any of them. Lockyer, Janssen and Frankland carried out further investigations of this bright yellow line, and, finding that it could not be ascribed to any known element, suggested that the name "helium" be given to the element producing it, a name derived from the Greek word meaning sun.

In 1888 W. F. Hillebrand, of the U. S. Geological Survey, in the course of his study of the mineral uraninite, found that when dissolved in acid it gave off a quantity of inert gas, which he concluded was nitrogen. In 1894 Rayleigh and Ramsay discovered in the atmosphere a new inert gaseous element to which they gave the name argon.

Helium in the Atmosphere

In 1895 Ramsay, through Sir Henry Miers, learned of the experiments of Hillebrand in obtaining an inert gas from certain uranium minerals, which was considered to be nitrogen. Thinking that perhaps this gas might contain argon, Ramsay obtained from Hillebrand for experiment a sample of the mineral cleveite (one of the uranium minerals) from which he extracted the gas by boiling the mineral in acid. After removing the oxygen and nitrogen the residual gas was examined spectroscopically with the result that the bright yellow line of helium was at once recognized. Its existence in the earth was announced to the world in a paper published in the "Chemical News" (vol. 71, p. 151, 1895) and in a paper read before the Royal Society, London, by Sir William Ramsay in the same year.

Further investigations by Ramsay disclosed the fact that other uranium-bearing minerals contained helium, as well as some of the rare-earth minerals such as monazite and thorite (thorium, cerium, lanthanum and didymium minerals). A few months after the discovery of helium in the uranium minerals its discovery in the atmosphere was announced by H. Kayser; also its presence in the gas emitted from the mineral springs of Wildbad, in the Black Forest, Germany. Subsequent investigations by a number of scientists has disclosed the fact that helium is widely distributed through the earth's crust, not only in many minerals and rocks but in mine gases and in the gases from many mineral springs and fumaroles.

The latest determination by Sir William Ramsay (1915) of helium in the atmosphere near the earth's surfaces places it at 1 part in 245,300 by volume; but that the proportion increases above the adiabatic layer (5 to 7 miles above the earth's surface) J. H. Jeans has calculated the theoretical proportions of the several gases at different levels in the upper (isothermal layer) atmosphere and concludes that at a height of 50 miles above the earth the heavier gases disappear and that the atmosphere consists of hydrogen, nitrogen and helium, with a small quantity of neon and oxygen, while at a height of 100 miles the atmosphere consists almost entirely of hydrogen and helium with very small proportions of the other gases.

Helium in Natural Gas

In 1907 Dr. H. P. Cady and D. F. McFarland of the University of Kansas carried out investigations into the nature and composition of natural gases from the Kansas fields, paying particular attention to certain gases that were non-inflammable owing to their large nitrogen content. In the course of these investiga-

tions it was found that many samples tested showed appreciable amounts of helium, particularly those having a large nitrogen content, some of which were found to contain as high as 1½ per cent. of the rare gas. The results of these investigations were made the subject of a paper by Cady and McFarland, which was published in the "Journal of the American Chemical Society (vol. 29, 1907, pp. 1523 et seq.); but aside from being of considerable scientific interest, no importance was attached to the discovery.

On February 28th, 1915, Sir William Ramsay wrote to Dr. R. B. Moore, who was at that time Chief Chemist of the Bureau of Mines of the United States, and who had previously worked with Ramsay in investigating the rare gases of the atmosphere, asking him about certain mine gases and stating, among other things: "I have investigated "blowers" — that is, coal-damp rush of gas — for our Government for helium. There does not appear to be anything in the English blowers, but I am getting samples from Canada and the States. The idea is to use helium for airships." Dr. Moore did not make any public comment on these remarks of Ramsay's because the United States was officially maintaining strict neutrality, even if many of her citizens were selling munitions to the allies; but he remembered the discoveries of helium in the Kansas natural gas and realized what it would mean to the nation that had large quantities for use in balloons and dirigibles.

War Stimulated Processes for Recovery

The Board of Invention and Research, London, realized the importance of having supplies of helium for the use of the army and navy for aeronautical purposes and invited Dr. J. C. McLennan, in 1915, to determine the helium content of natural gases within the Empire and to work out some practical method of recovering it on a large scale. In the investigations that followed Dr. McLennan was ably assisted by his colleagues of the University of Toronto and the Canadian Department of Mines. By 1916 a system had been worked out whereby it was possible to produce helium gas having a purity of 87 per cent., but considerable difficulty was being experienced in removing the last traces of the heavier hydrocarbons. Experiments were conducted with various types of rectifying apparatus and by 1917 considerable progress had been made and considerable quantities of helium of different grades had been produced.

During the spring of 1917 the United States decided to come into the war on the part of the Allies, and at a meeting of the American Chemical Society held in Kansas City in April of that year, Dr. Moore brought up the subject of helium for war-balloon use and its separation from natural gas, calling attention at the same time to the richness in that element of certain natural gases in Oklahoma and Texas. The matter was brought to the attention of the United States Bureau of Mines and they placed it in the hands of G. A. Burrell, who at that time was in charge of the Bureau's war-gas work. Mr. Burrell was aware of the rich helium gases of the Petrolia field, Texas, and a number of conferences were held with officials of the various army and navy departments interested, at which the question of helium production was discussed from every angle, and it was decided to go ahead.

Linde, Norton, Claude and Lacey Processes

Dr. Cottrell called Mr. Burrell's attention to th Norton process of extracting helium from natural ga and suggested that this process be tried. Mr. Norto was called to Washington in June 1917 and as a resul of the conference it was decided to erect an exper mental plant. It was further suggested that the Lind Air Products Co., the Air Reduction Co., and th Lacy process people be requested to coöperate with th Government of the United States in this helium undertaking. This suggestion was acted on and a the recommendation of the joint Army and Nav Board an appropriation of $100,000 was made to carr on this helium work under the direction of the Burea of Mines.

In the latter part of 1917 the British Admiralty sen Commander C. D. C. Bridge and Lieut. Commande S. R. Locock to go thoroughly into the helium ques tion in the United States and investigate its possibil ties, as they (the Admiralty) were very anxious t secure 100,000,000 cubic feet of the gas for immediat use and to contract for a further supply of 1,000,00 cubic feet a week. The arrival of this British com mission in the United States stimulated the interest o the U. S. army and navy authorities in helium an resulted in further appropriations being made so tha experimental plants could be built to try out the processes of the Linde, Claude and Lacy companies in addition to the Norton process already decided upon Of these experimental plants three were built, two a Fort Worth, Texas, one using the Linde and the other the Claude system; and the third at Petrolia, Texas, using the Norton process. All three plants produced helium and at the time the armistice was signed there were lying on the docks about 150,000 cubic feet of the gas, compressed into cylinders under a pressure of 2,000 pounds per square inch, awaiting shipment to France.

To be continued

PETROLEUM PARAGRAPHS

In east central Alberta the No. 2 well of the British Petroleums Limited, in the Wainwright field has drilled through 17 feet of oil-bearing sand at a depth of 2,019 feet. Casing has been set and a test will be made of the well shortly to ascertain the production. Considerable gas has been met with in drilling this hole.

The Imperial Oil Company's Grattan No. 2 well in the Irma-Wainwright field is having trouble with casing at a depth of 1,864 feet. Endeavours are being made to remove this casing so that the hole can be deepened.

R. T. Elworthy and R. J. Alford of the Chemical Department of the Mines Branch, Ottawa, have been investigating the natural gas in southern and east central Alberta with special reference to its utilization for the extraction of gasoline and in the manufacture of carbon-black under the recent regulations.

SEMI-DIESEL AIRPLANE ENGINE

A recent incident indicates the direction in which the problem of gasoline motor fuel is likely to be solved. The British Air Ministry has recently completed successful bench tests on a 750 h.p. semi-Diesel airplane engine, which soon will be tried out in the air. A similar engine of 1,000 h.p. is under construction.

REDUCTION IN GASOLINE PRICES IN GREAT BRITAIN

Gasoline prices, which underwent a reduction of ıbout 6 cents per gallon in July, were further reduced)n September 25 by 2 pence per imperial gallon,equivaent to 3¾ cents in American money per American galon. The latest reduction means that gasoline is now sold in Great Britain about 1 cent per gallon less than just before the war. At the termination of the war, :oward the end of 1918, the wholesale price of petrol n Great Britain was 3s. 4d. per gallon, but in December of that year the first reduction was made. The new retail prices are therefore less than one-half those ruling when hostilities ceased and show the extent to which the excessive stocks in the United States are affecting prices in this country. It is probable that the present reduction will seriously jeopardize the operations of some of the small companies in the petrol trade. —**Commerce Reports.**

PETROLEUM IN TASMANIA

A report by A. McIntosh Reid, Government Geologist of Tasmania, on the search for oil in that island contains the following summary statement: "The recent discoveries in the Mersey Valley district are very important, not only because of the prospects there, but because they lend encouragement to operators in other fields. Natural oil in commercial quantities has not yet been found, but seepages occur, and the geological conditions are particularly favourable."

OIL AND GAS IN FRANCE

The French financial weekly, **Radio-Midi**, states that there has been much activity in prospecting for oil in various parts of France in the last few months. The Ministry of Public Works organized a committee of scientists to study petroleum in France, and this committee formed a special branch to conduct geological researches. As regards the region included in the Bordeaux district, it is learned that a mission comprising three scientists has begun a survey in the Departments of Hautes-Pyrenees, Basses-Pyrenees, Landes, and Gers. The survey is expected to be completed in two months. The same publication on September 8 mentions that at Castagnede, Department of the Basses-Pyrenees, in one of the borings which exceeded a depth of 100 meters the discharge of gas is so considerable that the drilling is only proceeding at the rate of a few centimeters a day, instead of several meters as was the case when drilling through the bed of sand.—**Commerce Reports.**

TITANIA GLASS

At a meeting in Sheffield on October 17th of the Society of Glass Technology, a paper was presented by A. R. Sheen and W.E.S. Turner entitled. "The effect of Titania on the Properties of Glass." The paper first discussed the present interest in heat resisting glass, and pointed out that modern heat resisting glasses contained a high percentage of silica, and also boric oxide in considerable amount—**e.g.**, the well-known glass, Pyrex (which owed its high thermal endurance to its exceptionally low co-efficient of expansion, 0.0000032) contained approximately 80 per cent, silica and 12 per cent. boric oxide. There were, however, objections to the use of these oxides. In the case of silica the difficulty was merely one of obtaining a sufficiently high melting temperature. On the other hand, glasses containing boric oxide were very readily melted, but here the objection was the effect of the oxide on the durability of the glass. Recent research in the Department of Glass Technology of Sheffield University had shown that as the B_2O_3 content of a glass was increased the durability towards water and acid increased to a maximum, and then as the B_2O_3 content was further increased the durability fell off rapidly. Boric oxide containing glasses (and, of course, glasses with high silica content), on account of their acidic nature, were very readily attacked by alkali—**e.g.**, it was quite useless using Pyrex ware as an alkali container. What information there was concerning the use of titania in the production of glass seemed to point to the fact that titania glasses were heat reisting, but no experimental data were given. It was with this consideration specially in mind that this piece of work was undertaken.

At the outset preliminary tests were made to find out what mixture of silica titania and soda would give glasses at the highest temperature obtained in glass melting practice—**e.g.**, temperature of 1,400° to 1,450° C. There were indications during these melting operations that titania glasses were heat resisting. It was found in many cases that the glass could be removed straight from the furnace and allowed to cool down in the open air without splintering or cracking of the mass of glass occurring.

After considering the analyses of these six glasses, the first question dealt with was the durability of the titania glasses towards water. It was found on comparing with the corresponding lime and magnesia glasses, that the titania glasses were less attacked than the lime glasses, especially in the earlier members of the series. The durabilities of the titania glasses were found to be practically the same as those of the correspondent magnesia glasses.

The annealing temperatures were found to be rather less than those of the corresponding lime and magnesia glasses.

Next, the important question of thermal expansion was dealt with. The thermal expansions of these titania glasses (only the first four glasses of the series were tested) were only slightly less than those of the corresponding lime glasses. Therefore if titania glasses are heat resisting it is certainly not due to their having a low expansion, as is the case with Pyrex glass, for example, but the cause must be sought in some factor, such as tensile strength or elasticity. These glasses possessed good working properties, their viscosity increasing as titania replaced soda. Throughout all the glasses melted in connection with this work there was hardly any evidence of devitrification occurring. This bore out the statement of previous workers that titania hindered devitrification.—The Chemical Age.

LABOUR COST ON THE RAND

Treatment costs per short ton on the Rand were reduced from 25s 8d in 1921 to 23s 6d in 1922, due principally to the reduction of wages to white miners and a reduction in the number employed. White miners received 33s 9d per shift in 1921, and 23s 4d per shift in 1922, while native labour cost 3s 5d per shift. Another important factor in the reduction of working costs is the improved drilling efficiency due to the use of hammer drills, whose capacity is 6 or 7 holes per day against 4 for the reciprocating drill.

NEWS AND COMMENTS

By ALEXANDER GRAY

Eustis Making Copper Concentrate

Notwithstanding high freights and low metal prices the Eustis company of the Quebec Eastern Townships, is operating on a small scale, mining about 200 tons a day, making a 22 per cent. copper concentrate by differential flotation, and a tailing that should be sought by chemical companies for its sulphur content.

Coniagas and Newray

It is a doubtful compliment the daily press has been paying to the Coniagas company for "gambling" a million, if necessary, to make a mine of the Newray. Thus far, the expenditure does not exceed $125,000, and it may not be necessary to expend more than $500,000 before the mine will be ready for a mill. Somewhere, according to the daily press, between $125,000 and the million, "the Coniagas will have a big and profitable gold producer in the Newray."

Now, if there is one mining corporation in the Northland that has earned a reputation for conservatism in its quest for reproductive opportunities, it is the Coniagas. Reaching for chances to share their profits with the country that brought them wealth, Coniagas' chief owners may have "gambled", but that is hardly the word by which to designate constructive enterprise, however speculative.

Playing with surplus money with a purpose always has been a part of Coniagas policy. It went to Bruce Mines, had a try here and there, abandoned a Porcupine undertaking, has participated in South Coleman, entertained Larder Lake, gave consideration to Quebec—and now there is in Newray workings "considerable low-grade ore, with occasional patches of high-grade" — the latter being descriptively inept.

The very fact that the Coniagas is going ahead with development and permanent equipment, is an assurance that Newray is presenting sufficient inducements; therefore it has ceased to be a "gamble". Moreover, the company's representative in the Newray operation has known a good deal from the beginning about the underground conditions, for he directed a great deal of the development under other ownership and urged the provision of milling equipment. Consequently the structural features must have appealed to him, or Coniagas owners would not have taken the risk.

Gambling with their Own

More to the point, with reference to the Coniagas gambol — if the Newray development has an adventurous and playful aspect — is the importance of the extension of the Pearl Lake ore-bearing horizons. A year or two ago a shear zone was said to exist on the Holtyrex. Drilling had indicated something worthy of exploitation in the Newton. Duplications of porphyry intrusions, if not triplications, were intimated. Now it is stated that "there is a tongue of porphyry about 800 feet in length along the southern part of the central section of the Newray."

To prove the economic worth of that, is something of which Coniagas capital and technical staff is capable, and the outcome will be awaited with eagerness. Another mining area where it was not thought possible when the Rea was forsaken, and still another a result of the Vipond development below the basal may make scientific "gambling" the best sort o gamboling for those who can afford it.

Canadel—Oh Canadel!

Unauthenticated reports that the McIntyre Company is taking over the Platt Veteran Claim, and that the Lewisohn management of the Goldale is meeting with substantial encouragement at the 1,000-foot level recalls to mind that little has been heard of Canadel efforts to make a mine out of the Rochester Veteran Claim. The Lewisohn interest has the goodwill of all identified with the Porcupine camp. It has been thorough and has done more than it contracted to do. Should the Platt Veteran ground fall into the McIntyre lap, that may be one reason why President Bickell went to London, to place the shares that were optioned to New York people, and that have not been marketed. Possibly the Goldale development and that at the Vipond may have prompted the McIntyre to move on the Platt. At any rate, there will be nothing around Pearl Lake that will be unacquired by producing companies or those in a position to operate, should the Lewisohn management take over the Schumacher mill

This leaves the Rochester Veteran to serve its probationary period and be extricated from stock flotation methods deserving of severest censure. Not only was the Canadel a hodge-podge affair but it is well understood the property has not been paid for. The London prospectus represented that the Rochester title is vested in the Canadel combination. How the promoters got away with this is unexplained. As a matter of fact the purchase price is $175,000. Of this amount $75,000, or thereabout, has been paid. Other payments are due in the near future. Meanwhile work is proceeding at the property. If those who represented — or misrepresented — the actual owners, do not succeed in meeting the further installments, it is not unlikely there will be a warm half-hour or two in London.

Nothing ordinarily attempted by sleight-of-hand artists could excel the tactics of expert promoters. If London officials and subscribers countenance such things, crude manipulators who frame up "easy money" ventures without regard to the outcome, need not be punished — unless they are too rough about it.

PLATINUM IN THE TRANSVAAL

A platinum-bearing lode one hundred miles north of Pretoria, South Africa, has been traced for a distance of twenty miles, stated Mr. Max Baumann in a paper read in September before the Chemical, Metallurgical and Mining Society in Johannesburg. The average value so far disclosed is low, but a search is being made along the lode for ore of workable value. As is well known, platinum in small quantities occurs with gold in the banket of the Rand.

The United States now produces over 90 per cent. of the dyes consumed in the country; in 1914 imported dyes were 90 per cent. of the total used.

ELBOW LAKE GOLD AREA

Summary Report, 1922. *Part C*, of the Geological urvey contains a report by P. Armstrong, from which he following is abstracted:

The widespread interest aroused by the gold occurences in the Elbow Lake area, northern Manitoba, nade a detailed survey of its geology and mineral eposits desirable. This was carried out by the writer etween June 10 and September 10, 1922, and the reults are given below.

The area examined is shown in the extreme northast corner of the Geological Survey map of Athapauskow Lake area (No. 1726). It lies between 54°30′ nd 54°45′ latitude and is bounded on the west by 01° longitude. Its total areal extent is about 165 quare miles and comprises Elbow lake proper, with Webb and Hassett lakes lying to the northwest and ortheast respectively, and Claw lake to the southeast.

The camp first to public notice after the discovery y G. C. and K. C. Murray, early in 1921, of extremely ich gold ore on what is now known as the Murray roup, situated on the east shore of Elbow lake at point where Grass river leaves the lake.

In October, 1921. interest identified with the Hollinger Consolidated Gold Mines, Ltd., of Timmins, ook an option on this group and some adjoining laims. Their entry into the area was followed by hat of the Exploration Company, Ltd., of London, England, who optioned various claims in the northern art of the region. Meanwhile much and promisuous staking had taken place, so that at the time of he writer's visit almost no ground, mineralized or arren, within the area, was open for location. Unfortunately for the camp and the mining industry in general, most of the staking was done by relatively few men, acting under power of attorney for outside speculators. Hence it devolved on the two companies mentioned and a few experienced and energetic prospectors to prove the camp.

On June 10, 1922, the Hollinger interests suspended operations and have since allowed their option on the property to lapse. The Exploration Company also withdrew from the district definitely towards the end of August. At the end of the writer's sojourn in this ara only one or two prospectors were continuing to developtheir claims, but according to latest reports a new company, the Gordon Murray Gold Mines, Ltd. is operating the Murray group and some adjoining claims with a small force of men.

Economic Geology

This area offers no example of a true fissure vein, i.e. of a fissure of sustained length, depth, strike, and dip due to faulting or shearing of the country rock with simultaneous displacement, laterally, of the walls and filling of the spaces thus created. The closest approach of any of the deposits to this type of rock opening is found in the Murray group of claims. These deposits occur in a quarzitic gneiss which during the regional folding was sheared along closely spaced planes, 6 inches in width and generally of limited extent in their other dimensions. Numerous tension cracks, irregular in dip and frequently intersecting each other, also occur, sometimes widening out, where fracturing has been most intense, into larger openings now filled with vein matter. These fractures are too irregularly disposed, and too widely spaced, to be considered a sheeted zone. The Murray deposit is the only one found in this area located within a sedimentary bed, and is also the only representative of the type just described.

A second type is illustrated by the so-called "Garbutt vein," really a quartz porphyry dyke, of post-Amisk age, that cuts across the folded greenstones. During the ore-forming period this dyke was sheared, producing short, narrow, somewhat disconnected fissures or irregular shatter zones in which the vein material was deposited. The direction and intensity of movement are indicated by a border of finely laminated schist, 4 to 5 inches wide, on either side of the dyke and running parallel to it.

The third, and by far the commonest, type of rock opening is exemplified by the Sherlock claim, and shows the close time connection that must have existed between the folding process and that of ore deposition.

The Ore Deposits

Although only on one property, the Murray group, is the ore deposit situated in contact with the granite, no difficulty exists in ascribing the origin of the Elbow Lake ore deposits to the influence of the granite batholith. The position of the greenstone area, deep within, and entirely surrounded by, the granite; the absence of any other deep-seated igneous body, not directly connected with the granite, within the region; the high temperature character of the minerals such as tourmaline, zircon, pyrrhotite, arsenopyrite, are all evidence of this origin.

The deposits on the claims of the Murray group occur in a sedimentary gneiss which prior to the metamorphism of the region was a coarse, slightly feldspathic sandstone. Between this gneiss and the granite batholith which occurs close by is a broad belt of what was locally called a quartz porphyry, but under the microscope proved to be a quartz diorite and is considered to be a border phase of the granite and not a separate intrusive. During the folding attendant on the intrusion of the granite batholith, tension fractures developed in this gneiss. Some of these factures, subsequently, were filled by quartz containing pyrite and gold; others by an asemblage of pyrrhotite with tourmaline, orthoclase, and quartz. Individual veinlets yielded ore of extraordinary richness, but the fractures were small and far apart, and the pyrite with which the country rock is impregnated carries no gold values that might make profitable the mining of veinlets and country rock together.

PERSONAL AND GENERAL

Mr. R. M. Wolvin has spent a good deal of time recently in Sydney, attending personally to executive business in the head office of the British Empire Steel Corporation.

Dr. F. J. Alcock of the Geological Survey, Ottawa, lectured on Nov. 9th., before the Mining and Metallurgy Society of Queen's University, on the geology and physiography of Gaspé, and the zinc deposits at the Federal Zinc and Lead Mine.

Mr. Edward Godfrey, of Canadian Explosives, Ltd., has spent some time round the collieries of Cape Breton during the past few weeks, and conducted some very interesting and instructive tests with mining exposives.

Dr. E. P. Mathewson, of New York, has been elected a Representative Fellow of McGill University, his alma mater, by the graduates.

The Flinflon Copper-Zinc-Gold Ore

Description of the 16,000,000-ton Deposits in Northern Manitoba

By F. J. ALCOCK

The Department of Mines, Ottawa, has now published *Summary Report*, 1922, *Part C.*, which contains a 36-page report by Dr. F. J. Alcock on the Flinflon map-area, from which the following paragraphs are abstracted. The report is accompanied by a contoured map on a scale of 250 feet to the inch of the claims on which the Flin-Flon ore-body occurs, four horizontal sections at depths up to 735 feet, as determined by diamond drilling, and five vertical cross-sections. The regional map is not yet ready, and will be distributed later . The abstract follows:

Since 1913 the mineral belt north of The Pas, Manitoba, has attracted considerable attention. It has produced one important mine, the Mandy, from which over $2,000,000 worth of copper was recovered. Another ore-body, Flinflon, has been shown by diamond-drilling and underground development to contain over 16,000,000 tons of iron-copper-zinc sulphides carrying, in addition to the copper content, values in both gold and silver. Other sulphide showings in the region have also been staked. In addition to these sulphide bodies many claims have been taken up for gold. The more important of the gold-bearing veins yet located lie at the eastern end of the mineral belt in the vicinity of Wekusko lake. In 1914, the Geological Survey commenced mapping this whole region and by 1920 two sheets had been issued, covering the entire mineral belt. The first or western is on a scale of 3 miles to 1 inch, under the title of the Athapapuskow Lake region and the second, on a scale of 2 miles to 1 inch, is known as the Reed and Wekusko Lakes sheet. Recently need has arisen for more detailed geological information regarding the area, and the writer, consequently, was instructed to map an area of about 50 square miles surrounding the Flinflon and Mandy properties.

The area lies along the boundary line between Saskatchewan and Manitoba with approximately half in either province. It has a length in a north and south direction of 8 miles and a width in an east and west direction of 6 1-2 miles. The nearest point on the railway is the town of The Pas, Manitoba.

In 1913, the finding of gold-bearing quartz veins on Amisk lake caused a great deal of activity in that region. In the following year Woosey and Hackett found good quartz showings on the Kiski-Wekusko property at Wekusko lake, and active prospecting commenced in that part of the mineral belt. In the summer of 1915 the Flinflon ore-body on Flinflon lake was staked, and in the autumn of the same year the Mandy lens was located by Reynolds and Jackson. The latter property was taken over almost immediately by the Tonapah Mining Company, whose engineer, Mr. J. E. Spurr, was in the region at the time, and work was begun without delay. Active prospecting has been continued up to the present time and a great many claims have been taken up, both on quartz veins and on sulphide showings.

Geological History

The first event of which there is a record in the history of the region was a long period of great volcanic activity. Lava poured forth from fissures and craters covering wide areas of country. Volcanoes of the explosive type were abundant, and the ash and the coarser fragments from these gave rise to the beds of tuffs and coarse pyroclastic material that form common rock types in the area today. Acid and basic dykes derived from the same source as the flow rocks were intruded into the volcanic complex. adjacent regions sediments were locally being accumulated during the period of volcanism. These are now sedimentary gneisses and schists. In some places they are found underlying the volcanics; in others they overlie them; and in still other parts of the region they are interbedded with the volcanic rocks. These metamorphosed sediments have been named the Kisseynew gneisses in the Amisk Lake region, the Wekusko series in the Reed-Wekusko Lakes region, and similar rocks occur in several other areas of Manitoba. What the basement was, upon which these volcanic and sedimentary rocks were deposited is not known. Wherever their present base is found there is a younger granite which has come up from below and intruded itself into them. The finding of granite boulders in the very oldest sediments, however, points to the conclusion that the ancient terrain was, partly at least, granitic.

Deformation and intrusion followed this period of volcanism and sedimentation. The country was uplifted and a new cycle of erosion was inaugurated. The deposition of two series of sediments followed, a lower consisting dominantly of shale, and an upper one of arkose and conglomerate. Earth movements and an erosion interval separated the deposition of these two sedimentary series, called respectively the Lower and Upper Missi.

Granite Intruisions Bring Minerals

This period of sedimentation was terminated by folding and intrusion. The early intrusions were basic, and are represented by dykes of lamprophyre and gabbro cutting the Missian and older rocks. Then came the great batholithic invasions of granite, during which the country was uplifted and folded, and a mountainous topography was produced. In the late stages of the cooling of the granitic magma, solutions carrying iron, copper, and zinc sulphides were given off and, locally, replaced the older rocks, forming such ore lenses as the Mandy and Flinflon. In other places solutions carrying silica travelled along fracture planes and gave rise to the gold-bearing quartz veins. This period of intrusion extended over a long time. The earlier and later intrusives were basic. The batholithic masses were granitic, but all the intrusives were, probably, related.

Following this period of folding and intrusion came a long period of erosion. Little by little, through the action of rain, frost, and other destructive agents, the mountainous topography was worn down and the eroded material was carried away by streams. Steep-sided valleys gradually assumed more gentle slopes, and after a long period of time a flat-lying country of low relief rising gently back from the sea took the place of the former mountains. In this long period of erosion so much of the surface rocks of the region was removed that the granites, which had originally cooled at great depths, became exposed over wide areas of country. Only a few scattered remnants — commonly synclinal masses between granite batholiths — survived, to serve as the prospecting fields of the present day. The Flinflon area is part of one of the larger districts where these older rocks have survived.

Post-Cambrian Geology

Over this region of Precambrian rocks there swept, in the Palæozoic era, successive invasions of the sea. The chief of these took place in the Ordovician, when much of

ie interior of North America was flooded. In this sea ere deposited the limestones of Lake Athapapuskow re- ion. Other invasions took place in the Silurian and De- onian. In the Mesozoic era, sediments were deposited the southwest of the Flinflon area in the Pasquia hills nd they may even have extended over the map-area itself, ut if so they been entirely eroded.

In the Tertiary period the region was once more above ie sea, and undergoing erosion. Much of the covering of 'alæozoic rock was removed. At that time the country resented a great contrast to what it is like at present. lthough it had the same low relief, the streams were mooth-flowing, with no rapids or falls. There were no akes, and, in place of the bare rock-ridges such as are een today, there was probably a mantle of residual soil.

The last important event in the geological history of the egion, which gave the country its present character, was he advance of great sheets of ice from the northeast. 'hese removed the residual soil, smoothed down the topo- raphy, polished and striated the rocks, and, by dropping he débris irregularly over the region, dammed up river alleys and completely disorganized the drainage system. Numerous lakes were formed throughout the region.

During the latter part of the Glacial period, while the ce was disappearing, a great lake formed in front of the etreating ice-sheet. Clays accumulated in it and later ecame the great fertile clay belt of Manitoba. This old ake has been called Lake Agassiz; Flinflon area lies just o the north of its old shore-line.

Economic Geology

The ore deposits of the region are of three types: (1) opper-zinc-iron sulphide bodies; (2) gold-bearing quartz eins; (3) iron sulphide bodies. Only the first type has et proved to be of economic importance in Flinflon map- rea. The second type is important farther east at the Wekusko Lake end of the mineral belt. The deposits of ron sulphides are of no commercial value.

The map-area contains two important examples of cop- per-zinc-iron sulphide bodies. These are the Mandy and he Flinflon ore-bodies. The former of these was worked ntil the high-grade ore was removed. The Flinflon ore- body has been blocked out by diamond drilling and under- ground work so that its size and character are known, but no ore has been smelted.

Mandy Mine

Mandy mine is situated on a small peninsula on the west side of the Northwest arm of Schist Lake. Imme- diately after its discovery in 1915, J. E. Spurr acquired it for the Tonapah Mining Company. In the spring of 1916 a drill was installed, the first to be used in northern Manitoba, and by midsummer the entire ore-body had been blocked out and the values ascertained. It was found that there were 25,000 tons of massive chalcopyrite aver- aging about 20 per cent copper, with additional gold and silver values to the amount of $5 a ton, and about 180,000 tons of lower grade ore consisting of mixed copper, iron, and zinc sulphides running from 5 per cent to 8 per cent copper, 20 to 30 per cent zinc, and gold and silver to the value of $5 to a ton.

The ore-body was too small for a smelter to be erected on the property. Owing, however, to the war price of 26 cents a pound for copper, it was decided to commence min- ing operations immediately. The main difficulty was that of transportation. Mining machinery had to be taken in and the ore bed to be sent to Trail, B. C. to be smelted.

The ore was transported by trains across 80 miles of winter road, and then by barges to The Pas. Altogether 25,000 tons of high grade ore was thus handled. The amount and value of copper produced were as follows:

Year	Lbs.	Value.
1917	1,116,000	$ 303,329
1918	2,339,751	576,234
1919	3,348,000	625,775
1920	3,062,577	534,604
Total	9,866,328	$ 2,039,943

In addition to the copper the ore averaged $5 a ton in gold and silver.

The rocks on the peninsula on which the Mandy ore- body occurs are greenstone, pyroclastics, and chlorite schists. The ore lens is in a band of schist with massive greenstone on either side.

The lens is 225 feet long and has a maximum width of 40 feet.

Flinflon Ore-Body

The Flinflon ore-body is situated on the north shore of the southeastern bay of Flinflon lake, about 3½ miles northwest of the Mandy. It was located in he summer of 1915. Diamond-drilling was commenced in March, 1916, by New York and Boston interests and was continued by Toronto interests until 1918. In 1920 New York and Canadian interests conducted underground work from two shafts, which confirmed the diamond-drill results. In May, 1921, the Mining Corporation of Canada bought a majority interest in the property.

General Character

The ore-body lies in greenstone. To the northeast of the deposit the greenstone is massive and amygdaloidal, showing its flow origin. The ore-body strikes north 30 degrees west. Some banded tuffs associated with flow rocks on the summit of Flinflon hill east of the wagon road strike north 12 degrees west. The deposit dips from 60 to 70 degrees to the northeast and the boring records show that it pitches at a low angle to the south. Dykes of quartz porphyry were encountered by the drill; one of these dykes forms the hangingwall of the ore-body for some distance. The ore-body is a fairly regularly-shaped lens, tapering gradually to the northeast and ending rather bluntly to the southwest. As shown in the plans and cross-sections, it breaks up at the southwest end into two parts with minor mineralized zones. The total length of the ore- body on the surface is 2,593 feet; at a depth of 900 feet it has a length of over 1,000 feet. It has a greatest width of 400 feet, but this includes some bands of unmineralized greenstone which occur in the ore-body. The largest of these masses forms the prominent ridge along the strike of the ore-body between the two shafts. At a depth of 900 feet the ore-body has narrowed to 35 feet. It has been calculated that there are over 16,000,000 tons of ore with- out including the unmineralized horses of country rock or the ore below the 900-foot level.

Minerals of the Deposit

The principal minerals in the ore-body are pyrite, sphalerite, and chalcopyrite. Assays show that gold and silver are present. Arsenopyrite, galena, and magnetite have been recorded, and small amounts of native cop- per have been found in the upper part of the deposit. Quartz is present in places between grains of pyrite, and as local veinlets traversing the sulphides. Calcite is rare, but occurs in places with the quartz.

The ore consists of two fairly distinct types, known re- spectively as the solid sulphide variety and the dissemi- nated ore. The solid sulphide variety consists chiefly of very fine-grained, pale-coloured pyrite, containing spha- lerite, chalcopyrite with some rare fragments of schist, and some quartz and calcite. In places there is a distinct-

ly banded effect where the sphalerite and chalcopyrite form narrow bands in the pyrite. The sphalerite is dark in colour, and on the weathered surface assumes a bluish tarnish, probably due to the devolpment of a film of covellite. The disseminated ore consists of country rock, chiefly chlorite schist, impregnated with sulphides. The solid sulphide variety forms the central part of the lens, though in places it extends to the hangingwall, whereas the disseminated ore is largely confined to a zone along the footwall. Disseminated ore is also found on the hangingwall in the upper part of the deposit, but the copper content is here less than in the disseminated ore on the footwall. In places, as shown in both plane and section, disseminated ore forms a zone on either side of the central solid sulphide type. Boundaries between the disseminated and solid sulphide types are, as a rule, fairly distinct, though in places a gradation between the two varieties is found. Contacts between the solid sulphides and the horses of unmineralized rocks are also, as a rule, quite sharp. In places the disseminated variety of ore runs as high as 3 to 5 per cent copper, though the ore-body as a whole averages only approximately 1.9 per cent copper. The sphalerite is more abundant on the hangingwall side than elsewhere in the deposit. The average zinc content for the whole ore-body is about 3.8 per cent. The gold and silver values are, respectively, 0.074 and 1.04 ounces per ton. Galena is rare in the ore-body, but it has been found lining vugs in the country rock.

Origin

The deposit was, clearly, formed by replacement. The presence of unsupported masses of rock in the ore-body, some of them schistose with the plane of the schistosity parallel to that of the wall-rock, and the character of the disseminated ore, consisting, as it does, of country rock partly replaced by sulphides, can be explained only by this method of formation. It is clear also that replacement was along a shear zone.

The source of the solutions that caused the replacement is an interesting problem. There are two possible sources: (1) the basic igneous intrusives of post-Misian age; and (2) the granite of the region. It has usually been considered that the mineralizing solutions came from the granite. The chief argument in favour of this conclusion is the presence of quartz in the ore-body, showing that the solutions that caused replacement must have been silicious and hence more likely to have come from a granitic magma than from a basic one.

Aside from these occurrences of silica, the presence of gold and silver in the ore is suggestive of an origin from the granite. The gold-bearing veins of the region are clearly attributable to the closing phases of the intrusion of the granite batholiths, and it is probable that the sulphides were derived from the same source.

The solutions which brought the ore were hot. The wall-rock near the sulphide zone contains much sericite. Some of the more badly altered rock, near the ore-body, consists only of sericite, quartz, and pyrite. Irregular masses of talc, also, have been found in the chlorite schist and in the sericite schist of the footwall. It is to be concluded, therefore, that the deposition of the ore was the result of the replacement of a sheared zone in volcanic rocks by solutions from intermediate to high temperatures given off from the granite intrusives. The shearing took place during the period of folding that accompanied the granite intrusion, and the replacement occurred towards the close of the period of intrusion. The solid sulphide ore was formed first. Towards the close of the period of mineralization the solutions were relatively richer in copper and gave rise to the disseminated ore on either side of the solid sulphide mass.

Conditions Affecting Mining

To mine the deposit profitably it will be necessary t have a railway to the property, a smelter, and electrica power. There are also other requirements to be met, suc as securing sufficient flux material and determining th proper metallurgical processes to be employed for th solid sulphide type of ore. It is hoped that more or bodies will be discovered in the region to help bear th cost of a railway, smelter, and power-plant.

SAFE ELECTRICAL EQUIPMENT

The following pertinent questions regarding ele trical installations in mine are included in Serial N 2541 of the United States Bureau of Mines, which addressed to the safety engineer:

1. Is there some one in charge of electrical equi ment who is fitted for this position by ability, training and experience?

2. Is a systematic recorded inspection of electric equipment made at least once each month?

3. Is a plan map of the mine kept showing all pe manently installed electrical machinery and apparatu including cables, conductors, lights, etc?

4. Are there instructions for resuscitation from ele tric shock posted in each surface and undergroun electrical station, also at the entrance of the mine an in the first-aid station and are employees working o electrical equipment trained to apply these instruction in case of accident?

5. Are prohibitory notices posted wherever elec trical apparatus that should not be operated by un authorized persons is installed, and caution notice posted where such warning will be most effective i reducing the likelihood of electrical contact?

6. Are persons allowed to work on or with ele trical equipment of any kind before they have bee properly instructed in their duties?

7. Are the metallic frames, casings, and covering of stationary apparatus such as switch-boards, motor and transformers grounded, so as to prevent a shock hazard in case these parts become charged with an electrical current?

8. Are the metallic armors or coverings of cable and wires grounded, so as to prevent a shock hazard i case these coverings become charged from the circui which they carry?

9. Are the metallic sheaths and armors of electri cables electrically continuous throughout their length so that there can be no voltage difference between dif ferent sections?

10. Are power lighting, telephone, signal, shot firing, and trolley circuits properly installed?

11. Are trolley, power and lighting circuits properly guarded?

12. Are your switches, rheostats, fuses and circuit breakers well maintained and inspected?

Then there follow suggestions for the inspection o electric locomotives, hoists, drills, motors, portable lamps and other equipment.

MAP OF KEELEY-FRONTIER AREA

The Ontario Department of Mines has now available for distribution to those interested Map 31A—15, which shows the present productive part of the South Lorrain area on a scale of 400 feet to the inch. It will accompany C. W. Knight's report on the Cobalt silver area.

COAL OUTPUT FOR AUGUST

The Dominion Bureau of Statistics reports that the utput of coal from Canadian mines during August mounted to 1,5855,000 short tons, an increase of 60 er cent. over the tonnage for the previous month, nd 27 per cent. over the average for the month of he three preceding years. The output for the month howed increases of 489,000 tons in Nova Scotia, 98,000 ons in Alberta, 3,000 tons in British Columbia and ,000 tons in Saskatchewan. The cumulative output rom all mines for the eight months of 1923 amounted o 11,376,000 tons, an increase of 22 per cent. over he preceding three-year average for the same period.

Comparison of August and July figures covering he total importation of coal from the United States nd Great Britain showed an increase of 13 per cent. August imports amounted to 2,746,000 tons while in uly 2,445,000 tons was brought in. The August im-ortations this year were 65 per cent. greater than the hree-year average for the month. During the month 6,900 tons was imported from Great Britain. Total mportation of all coal for the eight months of 1923 vas 15,393,600 tons an increase of 55 per cent. over he preceding three-year average for the same period.

The total number of men employed in the coal mines f Canada during August was 28,670 of whom 21,516 vorked underground and 7,154 on surface as compared vith a total of 27,304 in July, of whom 20,202 worked nderground and 7,102 on surface. The monthly pro-luction per man was 55 tons for August as against 36 ons per man for July. During August the production er man-day was 2.34 tons. The "tonnage lost", mounting to 23 per cent. of the possible tonnage was lue in the east to absence of workmen and in the west o lack of orders.

REPORT ON MINING ACCIDENTS IN ONTARIO

Part 10 of the 31st report (1922) of the Ontario De-artment of Mines is now published. The fatal acci-lents during the previous year are recorded as 24, he same number as the previous year, and with the xception of one year (1915), the lowest since 1908. The rate per thousand was 2.54, which is somewhat elow the average rate. As the hazard in gravel pits nd quarries is unusually great, a special inspector was appointed in charge of them with a view to im-roving this record.

The volume includes also a brief description of the mines and prospects visited during the year by the corps of inspectors, giving the resident staff and the financial directorate of each. In the case of the more important mines operating data are included. A short report on the Instruction Classes for Pros-pectors conducted by Dr. W. L. Goodwin is given, describing the resumption of these classes by the Department of Mines after an interval of fifteen years. Some brief notes by the late Joseph Keele on clays on the Missinaibi River conclude the volume.

MINE VENTILATION

A study of the relative value of canvas and gal-vanized iron pipe for metal mine ventilation by fans conducted last winter by the United States Bureau of Mines in the mines of the Anaconda Copper Co., is described in Serial No. 2540. Friction and leakage losses are less with canvas pipe, which is, on the whole, more satisfactory than metal pipe, though it does not last so long.

PURIFICATION OF ALUMINUM SULPHATE SOLUTIONS

The success of experimental work on the purification of copper sulphate solutions and zinc sulphate solutions, made at the Pacific experiment station of the United States Bureau of Mines, suggested that possibly aluminum sulphate solutions could be purified of iron compounds and thus provide a much needed cheap process of producing iron-free alum and other aluminum salts which are now twice as costly as the less pure salts and yet are used in large tonnages by the baking-powder makers and the paper mills, and for water purification. At present, deposits of clay low in iron are the only ones that can be used for chemical purposes. Three different modifications of a laboratory method for hydrolytical removal of iron from aluminum sulphate solutions were worked out. Further experimentation is being conducted with a view to developing this method into a practical process for preparing pure alumina direct from clays for use in the aluminum industry.

B.C. TOPOGRAPHIC MAPS

The Geological Survey, Ottawa, has published two contoured topographic maps of British Columbia areas on a scale of a mile to the inch. No. 1996 covers an area of about 150 square miles astride the North Thompson river 60 miles north of Railways. No. 1897 shows the banks of the Coquihalla river for 40 miles northeast of Hope. Both have a 100-feet vertical contour interval.

WORLD MINERAL STATISTICS

The publication of world mineral statistics covering the period 1919-1921, by the Imperial Mineral Resources Bureau is proceeding steadily. Those on gold, silver, tin, coal coke and by-products, zinc, and petroleum are now available, and the remainder will be issued shortly.

STONE-DUSTING FOR SAFETY

Mr. George S. Rice of the United States Bureau of Mines, has presented a paper on "Coal Dust as an Explosive Agent" before the Mining Institute of Scotland. In this summary he says: "The watering method I now look on with apprehension; stone-dusting appears difficult and expensive under American conditions, but it now seems to be the safest plan. I am hopeful that the quantity of coal-dust to be treated will be greatly diminished by the use, say, of tight pit-cars or tubs, and possibly even by the use of tight covers, hinged or tightly clamped on over the top of the pit-car or tub. While this seems difficult, it is, after all, no greater step than going from loose and open-end tubs to tight-end cars."

THE ROCKS OF TORONTO AND VICINITY

Part 3 of the report on the stratigraphy and paleontology of Toronto and vicinity, by W. A. Parks and Madeleine Fritz, has been published as Part 9, Vol. 31 (1922) of the Ontario Department of Mines. It contains a detailed description, illustrated by plates, of the fossils found in this vicinity.

FINAL COAL STATISTICS FOR 1922

The Dominion Bureau of Statistics has now published its finally revised statistics on Coal in Canada for 1922, which is available on request by those interested.

Industrial Items

BABCOCK-WILCOX AND GOLDIE-McCULLOCH LIMITED UNITE

The important announcement has been made that Babcock and Wilcox, Limited of London, England and the Goldie and McCulloch Company Limited of Galt and the Babcock and Wilcox Company of New York have organized a new Canadian company under the name of Babcock-Wilcox and Goldie McCulloch Limited with head office and works at Galt. The capitalization of the new company is three million dollars and it will have branch offices in Vancouver, Winnipeg, Toronto, Montreal and the eastern provinces.

R. O. McCulloch is the president of the new company. A. G. Pratt of New York, is chairman of the board of directors, A. R. Goldie is vice president, and Alex. C. Fleming, secretary. The other directors are Sir James Kemnal, managing director of Babcock and Wilcox, Ltd., London, England; W. D. Hoxie, president of Babcock and Wilcox Company of New York. E. H. Wells, chairman of the board of the Babcock and Wilcox company of New York, and A. W. Atwater, K. C., of Montreal.

The new company has acquired the Canadian business of Babcock and Wilcox, Limited and of the Goldie and McCulloch Co., Ltd. except the vault, safe and safety deposit manufacturing business of the later company. The new company will continue the manufacture of high grade boilers, super heaters economizers, stokers and boiler accessories and engines, pumps, turbines, condensers, etc. at their works in Galt. The Goldie and McCulloch Co. Ltd., will continue to manufacture and deal in valuts, safes and safety deposit boxes at the city of Galt.

The Babcock-Wilcox concerns are the largest manufacturers of steam boilers and land marine superheaters in the world besides being important producers of chain grate stokers, steel economizers, coal and ash conveyors, soot blowers and electric cranes.

The principal works of Babcock and Wilcox Limited are at Renfrew, Scotland, where about 5,000 hands are employed and they have branch works at Dumbarton, Scotland, Oldbury, England and in Italy, Australia and Japan. There also allied companies operating in France, Spain, Germany and Prussian Silesia. Branch offices are maintained in England and Scotland and at Brussels, Milan, Amsterdam, Sydney, Melbourne, Mexico, Lima, Rio de Janeiro, Bombay, Calcutta, Tokio, Johannesburg, Shanghai, Warsaw and Moscow.

The Babcock and Wilcox Company have their head office at New York and works at Bayonne, N. J., and Barberton, O., and they in addition a tube mill at Beaver Falls, Penn. where they manufacture boiler tubes. This company employs 3,500 hands.

The new organization will have the benefit of all the patents of the constituent companies as well as of the experimental and scientific work, the wide experiene and engineering knowledge of the British and American companies.

In making the announcement of the completion of the large transaction R. O. McCulloch stated that the safe works would be operated as an independent company under the name of Goldie and McCulloch Co. Ltd. In the meantime they will use the present plant but it is expected that eventually this industry will be housed in a separate plant.

When giving the details for publication Mr. McCulloch said that Babcock and Wilcox Ltd., the Goldie an McCulloch Co. Ltd., and the Babcock and Wilcox C desired to extend to their clients their grateful thank and appreciation of the confidence extended to them the past and expressed the hope that the new compan would continue to deserve and receive it in the future.

Business Started in 1859

It was in 1859 that the late John Goldie and the la Hugh McCulloch purchased the Dumfries Foundry fro James Crombie. The business experienced a stead growth and prospered. It remained a partnership unti 1891 when it was turned into a limited company, th first president being the late Hugh McCulloch, Sr. H was succeeded in 1910 by his son the late Hugh McCul loch, Jr., who remained president until his death in 191 when the present occupant, R. O. McCulloch, was elect to the office.

The late John Goldie was elected manager of Goldi and McCulloch Co. Ltd., in 1891 and on his death i 1896 he was succedeed by his son, A. R. Goldie who sub sequently became vice-president of the company.

The Magnetic Manufacturing Co. of Milwaukee, Wis has recently put on the market a new type "Hig Duty" Bi-Polar Suspended Safety Magnet, designe especially to remove tramp iron and steel from con veyed material. Its primary object is to protect crushing, grinding and pulverizing machinery from damage. It is of simple design and rugged construc tion and should prove useful in many cases in the mining industry.

EFFECT OF CARBON MONOXIDE ON REFRACTORIES

Large-scale experiments with an electrothermic dry distillation process for the treatment of zinc ores, re cently undertaken by the Mississippi Valley Exper ment Station of the United States Bureau of Mines were hampered by the rapid disintegration of con denser linings made of ordinary firebrick. A study of the problem developed that the action of carbon monoxide was largely responsible for the disintegra tion, due to the increase in volume caused by carbon deposition around particles of iron oxide contained in the refractory material. Thus the trouble can be avoided by the use of iron-free refractory material Silica brick or high-grade firebrick free from iron were found to be satisfactory. Results of these expe riments have widespread application as refractory brick must withstand the action of carbon monoxide gas when used in coke ovens, in iron-blast furnaces, in producer gas flues, and in the checker work of re generative furnaces fired with producer gas

THE MINING DISTRICTS

By THE JOURNAL'S CORRESPONDENTS

NORTHERN ONTARIO

Cobalt. — The Coniagas has decided to change its cal year from October 31st to December 31st, and interim report has been issued covering the eleven nths ending September 30th. It is stated that the mpany will reach its objective of 1,000,000 ounces for 12 months, and production costs compare favorably th those of the preceding year. In Porcupine, the wray Mine has been unwatered and a considerable ount of work done.. The new three-compartment aft has been completed to the 400-foot level and will continued to a depth of 1,000 feet, at which point ploration on a large scale will be started. To date out $117,000 has been expended on this property. A tal of $116,000 has been spent on the Beaver-Badger d Prince-Davis properties at Cobalt. Operations ve been carried on in the upper levels of the Beaver, om which ore for the mill is being produced. A osscut has been driven at a depth of 1,200 feet, near e lower contact, in order to explore this area. While e operations at the Beaver have not yet resulted in profit, it is hoped that with the additions to the mill w being made, a profit will be realized. The com- ny states that the options taken on properties in e Rouyn and Kowkash areas have been allowed to pse.

C. W. Price, of Cobalt, has entered an action against nson Clements, the finder of the big silver nugget scovered a short time ago in the Gillies Limit. Price ates that he is the owner of the nugget, which was moved from his mining claim.

After carrying on underground operations at the Ge- sse for a number of years, with discouraging results, ie operating company has recently found a shoot of igh-grade ore, which gives considerable promise. everal tons have already been produced and it is xpected a carload will be ready for shipment in a few eeks. An ore-sorting plant has been erected and ore active operations will now be carried on. This iscovery is of considerable importance to the conglo- erate areas in Bucke Township, as it is one of the w finds made immediately north of the 64 fault of he Nipissing, which is generally believed to have cted as a barrier for the silver-bearing solutions.

Good results are now being got by the old Colonial ompany, now known as the Menago Mine. A con- iderable amount of high-grade has been found in the tope recently opened above the 930-foot level, and to ate about 13 tons have been sorted out. The mill re is being shipped to the Mining Corporation for reatment.

South Lorrain. — At the annual meeting of the Hur- nian Belt Company, held in London a short time ago, igh hopes were held out for the development of the Maidens property in South Lorrain. This property is eld by the Canadian Lorrain Silver Mines, Limited, n which the Huronian Belt Company has a controlling interest. The interests associated with the Huronian Belt Company were responsible for the development of he Keeley, and it is believed that conditions at the Maidens are similar to those on the former property. Several veins, carrying silver, have been found, and although it was not to be expected that, at the horizon at which the work was done, any large quantities of silver would be found, increase in values, with depth, has been shown and the workings are still a considerable distance above the contact, where the company believes a zone of enrichment may be found. The Huronian Belt Company owns several claims adjoining the Murray-Mogridge, and it is reported to have taken an option on this property, and is unwatering it. A shaft is sunk to a depth of 200 feet on the Murray-Mogridge, and drifting on that level gave encouraging values.

Mining Corporation Report. — An interim report, dated October 15th, has been issued by the Mining Corporation. The report states that owing to the discovery of new veins and the extension of old vein systems, the Cobalt properties will not be worked out this year, as expected. Production for the year from the Cobalt properties will amount to about 800,000 ounces. The company has a lease on the Peterson Lake, in which some small veins of high-grade ore have been found. To date about three thousand tons of ore has been shipped to the mill. In South Lorrain a new three-compartment shaft has been completed at the Frontier and work has been started from the 5th and 6th levels. It is expected that important results will be encountered from this development work within the next month. Production continues at a satisfactory rate and no effort is being made to create a large production, the attention of the management being concentrated in the development and exploration of the property. Last March the company purchased three claims adjoining the Keeley on the south, and formed a separate company called the Lorrain Trout Lake Mines, Limited, with a capital of 1,500,000 shares of $1.00 each. In view of the heavy expenditures the Mining Corporation was under in South Lorrain, a two-thirds interest in the new company was sold at a price sufficient to more than re-imburse the Mining Corporation for the purchase price, and in addition provided $150,000 cash for the treasury of the new company. A condition of the sale was that the Mining Corporation should retain the management of the new company. A shaft has been sunk to a depth of 275 feet, and silver values were encountered for practically the entire distance, the ore taken out of the shaft being more than sufficient to pay for all the expense of development to date. The company also holds options on 13 claims in the Gillies Limit, on which exploration work is being done. Promising veins have been found and a shaft is being sunk on one of them, but the report states that it is too early to make predictions as to the ultimate value of the properties. In Manitoba geological work was carried on in the Flin Flon area, and 19 claims were staked. These new claims cover possible extensions of the Flin Flon ore bodies and control desirable smelter, mill and town sites and protect the water supply. The situation in Russia is such that it is impossible to estimate the value of the company's property in that country.

The Ontario Government recently ordered preliminary surveys for a railway to South Lorrain, and

has now decided to have a complete survey and location made, and route chosen being that from Cassidy, three miles South of Cobalt. This does not necessarily mean that the railroad will be built, but it will give the government the necessary information on which to make an estimate of the cost.

Kirkland. — Good progress is being made in the development of the Tough-Oakes-Burnside properties, and the main shaft has reached a depth of 900 feet. A new discovery has been made on the 800-foot level in hitherto unexplored ground, which gives indications of being the most important find this year. In addition to a 10-inch pay streak running $80.00, lower values are found over a width of several feet.

Lake Shore has declared a quarterly dividend of 2 per cent, payable November 15th to shareholders of record November 1st.

Porcupine. — McIntyre is reported to have purchased the Platt Veteran claim, at a price in the neighborhood of $400,000. The Platt adjoins the McIntyre on the south and the Schumacher on the east. Some years ago it was diamond-drilled by the Coniagas Company, and while wide mineralized areas were found, the values were very low. It is now believed, however, that ore may be found at depth, as was the case with the Schumacher, which was purchased some time ago by the Hollinger. Mr. J. P. Bickell, President of the McIntyre, is in England and it is believed he may be arranging for the sale of the unissued shares of the company's treasury stock. When the question of increased dividends came up at the last annual meeting, officials of the company stated that the company would shortly be faced with very large expenditures for the sinking of a 5,000-foot shaft and for the necessary equipment, and that to finance these expenditures the money would either have to be provided out of surplus or by the sale of securities. If it were provided from the earnings of the company, increased dividends would have to be deferred for a considerable time. In view of the reported purchase of the Platt it is likely the company is considering seriously the sale of its treasury stock.

Gowganda. — Castle-Trethewey is going ahead with its mill construction, and is making every effort to get the foundations in and the mill building up before the really bad weather sets in. To this end, underground work has been practically stopped in order to utilize the mine crew. Recent developments at the property have been very favorable, and it is understood there is over 2,000,000 ounces of silver in reserve. Mill heads are expected to be in the neighborhood of $50.00 a ton.

BRITISH COLUMBIA

Iron from Smelter Slag. — Interest in the recovery of iron from waste smelter products has been revived by experiments that are being conducted by the Granby Consolidated M. & S. Co., at their works at Anyox. Mr. H. S. Munro states that some encouraging results are being obtained on a laboratory scale. The large amounts of iron that are being wasted in the process of copper smelting have been pointed out repeatedly, an example being cited by Dr. Stansfield, who estimates, in his report to the Royal Ontario Nickel Commission, that 400,000 tons of metallic iron was lost in the production of 22,700 tons of nickel and 14,400 tons of copper from Sudbury ores in 1914.

Advances in Portland Canal Area. — Mr. George Clothier, the Government Resident Engineer for th Northern District, sums up his impression of the las season's work by saying that wherever sufficient ca ital has been available for development, satisfactor results have been obtained in the Portland Canal div sion, and cites the achievements of the Premier, Du well, Indian, Big Missouri, Outsider and B.C. Silve properties. He anticipates that the Outsider propert will be shipping to Anyox before the end of the yea and that the Dunwell and Indian Mines will be adde to the list of shippers next season.

The Premier Company are said to be doubling the treatment plant.

A large amount of diamond drilling and surface prospecting has been done in the district this year an Mr. Clothier is optimistic as to the future. The Home stake Mining and Development Co. has been doing good work on its property at the head of Kitsault river, and investigations are under way at the Bea group on Kitsumgalum lake.

Progress in Yukon. — Captain George Black, repre sentative of the Yukon Territory in the House of Com mons, Ottawa, arrived from the North en route east ward during the latter part of October and reported that the placer output of the Yukon this year would be up to par and that the silver mining industry at Mayo was prospering. Both the Keno Hill Ltd., and the Treadwell-Yukon companies at Mayo, he said, have done well in the short time they have been operating, despite pioneering difficulties involving heavy expenditures. Both have large quantities of ore in sight and the camp is facing a busy winter Capt. Black continued: "Now that transportation facil ities have been improved, operating costs are declin ing and profits consequently will be greater. So far only high-grade ore has been shipped, but I understand that both companies are planning to erect concentrators in the spring. This will permit of the handling of lower-grade ores and will substantially in crease production. A number of individual operators with high-grade ore in sight will work this winter. The companies are prepared to pay cash at the mine for ore, deducting the cost of transportation and smelting. This makes it possible for miners to operate who otherwise would be held up through lack of money. All this ore is being produced by United States' capital and goes out of Canada to smelters in the United States. The Canadian smelters do not offer attractive terms and Canada is not getting the benefit that might be expected from a purely Canadian product."

Granby Wages Reduced. — H. S. Munro, vice-president and general Manager of the Granby Consolidated Mining and Smelting Co., states that the Copper Mountain mine and the Allenby mill will be closed until the copper market improves. Employees, who went from Anyox to this mine and plant, will return to the company's northern operating centre. Notice also has been given that, owing to the low price of copper, wages must be reduced and this re-adjustment will be effective on and from the 15th November next. This means that the scale of wages under which the company was operating prior to March 16th last will again be applied.

Objections to Tax.—There is a possibility that the Act passed recently by the Government of the Province of Alberta imposing a tax on mineral lands of that Province will be disallowed by the Dominion Government. Several of the land owners seriously af

ected, among whom are the Hudson's Bay Company, he Canadian Pacific Ry., and the Edmonton Land ompany, are petitioning against the measure at Otawa on the ground that it is unconstitutional and unreasonable and designed, not so much to derive revenue as to confiscate mineral lands. The Province akes the position that it is a form of direct taxation hich it is fully empowered to impose.

Coal Mining Depressed. — "Due to the competition f foreign fuel oil, the coal industry of the Province s in a depressed condition." This statement appeared n the Speech from the Throne at the opening of the egislative Assembly of British Columbia. Whatever ay be said, regarding the cause of the depression, hether it is wholly or only in part attributable to he increasing use of fuel oil in the Province, there is o doubt that the coal trade is slack and that the industry is suffering.

Since last March the coal mines of Vancouver Island ave been working about two-thirds time, while the verage for the year to date is approximately three-uarters time. In the Nicola-Princeton field the Middlesboro Collieries have been running some fifteen days a month, but the Coalmont Collieries, in marked ontrast to other producing mines, has been working lmost full time. At Coal Creek, Crow's Nest Pass, he mines have been working about 20 days a month ince the beginning of the year, the Michel Collieries ave been able to get in two-thirds time, and the Corbin Coal & Coke Co., an average of half time since the eginning of the year.

A comparison of the production of the different coal ields of the Province for the first ten months of 1923 ompared with the same period last year shows that n Vancouver Island there has been a decrease of 166,006 tons; in the Nicola-Princeton field a falling off f 35,343 tons; while in the Crow's Nest Pass there as been an increased output of 161,980 tons. The mprovement indicated by the last figure is accounted or by the fact that in 1922 there was a three-months trike in the Crow's Nest Pass, while this year no labor rouble has interfered with the activity of the mines.

Welsh Anthracite for Vancouver. — In Vancouver, he suggestion that ships coming to the Pacific for grain and other cargoes for Europe should carry Welsh anthracite coal for sale in the West is meeting with favor. It is believed that the demand for shipping to carry Canadian exports would be more readily met f Pacific bound vessels were assured of a market for British coal which they might, under the circumstances, take on as distress cargo at such low transportation rates as would permit the fuel to enter into competition with the local coal. The possibility of the proposal is being investigated and some business men are confident it is practicable.

NOVA SCOTIA

H. J. McCann's Appointment. — Mr. H. J. McCann has been appointed General Manager of the Dominion Coal Company in the re-organization now taking place. Mr. McCann came to Sydney in 1899 and was with the Dominion Iron and Steel Company until 1904 when he went over to the Dominion Coal Company as a member of the executive staff. Later he returned to the service of the Steel Company and for years was Purchasing Agent. After the formation of the British Empire Steel Corporation he was in charge of all purchases for both companies and of the negotiation of contracts for all additions to their plant and equipment. He was assistant to Mr. Workman during his term of office as president and later he was made Assistant General Manager of the Dominion Coal Company.

There were very trying years, as there was much reconstruction to be done after the war ended. It took a firm hand and a clear head to keep off the shoals and rocks and to steer an even course. No doubt a man of less self-confidence, determination and mental capacity would have been swept away by the turbulent currents of these years. Mr. McCann came successfully through them, not without loss of physical energy, but with his mental vigor unabated, and with a larger experience of men and affairs. Five years of such life in such a time may have placed him in a position where he was misunderstood by his workmen. Certain it is he was not misunderstood by the Corporation he serves, who know that every ounce of the energy and all his faculties and extraordinary ability has been spent in their service. Mr. McCann holds very generous views of how workmen should be cared for and treated, and possibly in time when he has had an opportunity to work these out, he may be more fully appreciated.

Mr. Wolvin Announces Pension Scheme.—President Wolvin of the B. E. S. Co. did a most generous act when, without solicitation on the part of the workmen, he freely and voluntarily offered a pension to old employees of both Steel and Coal Companies. Such deeds on the part of a large corporation are calculated to form and cement a friendship between employer and employee which will go far to tide over the difficult days when trade depression bears on the spirits with a weight that eats into the heart and creates much bitterness. They present another side of the "soulless corporation" from that which we have been taught to know. Already the faces of aged workmen are lit up with the smile of a new hope—glad news has wakened a song where care had dwelt before, and the deep gloom pictured by Canon Scott has vanished before this earnest of a better day.

This pension plan provides for a pension payable:

(1) To any male employee who has been 25 years in the service and has reached the age of 65 years or more and who is retired from service either at his own request or the request of the employing officer.

(2) To any female employee who has been 25 years in the service and has reached the age of 55 years or more and who is retiring from service either at her own reques tor the request of the employing officer.

(3) To any employee who has been 15 years in the service and who during the course of his employment has become permanently and totally incapacitated for further service.

(4) The Board of Directors of the Corporation may at its discretion instruct and direct the Pension Committee to include in the pension scheme employees whose length of service has not reached the limits above provided for or employees who may, for other reasons be ineligible, for pensions under these regulations.

The amount of pensions payable monthly to persons retired under the provisions of the fund will be at the rate of one per cent. of the average monthly pay received by them during the last 10 years of their service multiplied by the number of years of their entire service.

To illustrate the working of these rules consider an

example: An employee has been in the service 30 years and during the last 10 years has received $1,000 per annum or $83.23 per month. His monthly pension would be one per cent. of $83.33 or $0.83 multiplied by 30, which equal to $25, provided, however, that no pension shall be more than $75 per month.

This fund will be administered by a Pension Committee appointed by the Board of Directors.

A. S. MacNeil Promoted. — In announcing the appointment of Mr. A. S. MacNeil General Superintendent of all the mines of the British Empire Steel Corporation, Mr. Wolvin said: "Although Mr. MacNeil is still in the prime of life, he has to his credit thirty years of uninterrupted service in coal mining. From a working miner he has advanced through every stage of training and experience to his present responsible position. His career is a striking example of the opportunity that is open to Nova Scotians who have the brains, the vigor and the determination to aspire to and attain positions of the highest responsibility and importance and to take their places in the ranks of those who are doing their part in developing the wonderful resources of their native province."

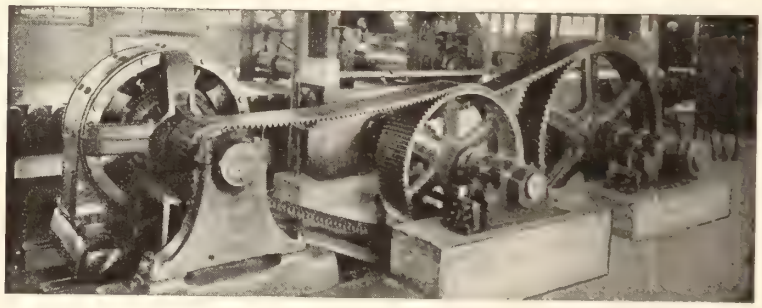
The *Canadian Mining Journal* has had some good things to say of Mr. MacNeil in the past, and is pleased to see that he is still rising in his profession, and trusts he may continue until he reaches the top.

Provincial Police a Useful Body. — The Commission to investigate the strike that occurred at the steel works last July has heard some startling evidence during their sittings. F. W. Gray presented the case for the Corporation, reviewing it from the beginning to the end. The prolonged agitation leading up to the strike, the division in sentiment among the workmen, the mob violence after it began, the desperate attempt of armed and masked workmen to intimidate all workmen refusing to strike, the precarious position of the coke-ovens and the attempted destruction of the water mains by dynamite, makes alarming reading even at this late date. The effective work of the mounted Provincial Police stands out prominently to the credit of the Province and points the way to the proper protection of Provincial industries in future struggles. Students of the case have no hesitation in stating that a Provincial body as formed last July is better fitted to give protection than the military forces. They are more mobile and their training, being along different lines, enables them to act quickly and deal with each situation as it arises more promptly than the soldier. If the work of the Commission does nothing else than give the public an insight into the true condition of affairs at the steel plant, it will have done much to prove the necessity of the protective forces used at that time.

Walter Herd is Chief Mining Engineer.—Mr. Walter Herd has been appointed to the position of Chief Mining Engineer of B. E. S. Co. Mr. Herd is well equipped for his duties, which lie in a very difficult coal field and which require just such training and experience as he has had in British collieries. His success in the undersea areas of Cape Breton is well known, as is also the success attained in the Springhill collieries, where he advised a change in the method of mining to meet bump conditions. The thick coal seams of Pictou county present sufficient complex problems to take up the time of any engineer, yet they now form only a part of Mr. Herd's extensive territory.

MORSE CHAINS

THE MORSE "ROCKER JOINT"



A few of the Morse chains in use at the Raymond Lead plant

Using chain drives speeds up production, cuts belt expense and overtime wages and operates with practically no repairs.

Write for Booklet

CANADIAN AGENTS

Jones & Glassco, Regd.

MONTREAL, TORONTO.

O.W. Ludwig, *Plant Superintendent of the Raymond Lead Co., Chicago, says:*

"Thirteen years of service without a repair is our experience with two 100 H.P. and ten 20 H.P. Morse Silent Chain Drives

"When we moved into our present plant thirteen years ago, we installed the present Morse equipment of silent chains for our two lead mills and ten hydraulic pumps. We had always previously used leather belts, but not without considerable trouble. For instance, if the operator was not careful — and gave the motors too great a load, the leather belt would slip and in some cases burn out. While with the Morse Chain Drive we overload them at times up to 15 H.P. without the slightest trouble.

"When we used leather belts on the hydraulic pumps, if a pump packing suddenly gave way, the water would squirt all over the pump as well as adjoining pumps, causing the leather belts to get wet. This often necessitated a shut-down on 3 to 4 pumps to dry out each belt, thus causing a loss of time by the men, which resulted many times in paying overtime to catch up on the work. Of course, with our Morse Chain Drive we have no such trouble—this positive drive prevents slippage and is not affected by water.

"Leather belts lasted us 2 to 3 years at the most, while our Morse Chain Drives have already lasted 3 to 4 times that long and seem good for many more years. So Morse Drives have cut our expense materially, speeded up production, cut out overtime wages and saved floor space, for they operate on shorter centers."

CRANE EQUIPMENT GIVES THE ASSURANCE OF UNFAILING SERVICE FROM THESE PIPE-LINES OF A LARGE FURNACE PLANT

WHEN DEPENDABLE STEAM PIPING COUNTS

Steam pipe-lines located in tunnels or basements or buried in the ground must give dependable service at all times. Crane valves, fittings and pipe bends for such installations are designed and produced to stand up under the most extreme conditions. Only selected materials are used in the manufacture of Crane equipment. Production operations are checked by rigid inspections, and searching factory tests guard uniform quality in the finished units. This careful factory practice gives exceptional endurance to Crane piping equipment.

The contributing factors in making good Wire Rope are:

Men who know how
The best grade of materials
The most Modern Machinery

We have all 3 and are producing the goods. Give us a trial.

Our Wire Rope Catalogue is an invaluable reference book and contains many helpful ideas on the care of wire ropes and cables as well as information on the best kind of rope to use on all classes of work. A copy sent upon request.

Our other lines of Manufacture are Wire Cloth for all uses, Perforated Metals, Wire Pulp Mats, Clothes Lockers, Machinery and Window Guards, Pulp Mats, inquiries solicited.

"Sullivanize" Your Drill Steel

Sullivan Sharpeners and Steel Heating Furnace

DON'T handicap your rock drills or delay your runners by using steel that is improperly heat-treated, badly formed or poorly sharpened. Train your Blacksmith to put as much footage as possible into each steel he on the job.

Sullivan Furnaces and Sharpeners Provide Drill Steel Quality Insurance

The *Sullivan oil or gas Furnace* heats the steel gradually, evenly, while electrical devices prevent overheating or burning, and indicate, also if the steel is not hot enough for working or tempering.

The hammer-forging action of the Sullivan Sharpener refines the grain of the metal, and with each repeated sharpening renders it tougher, less liable to wear or breakage. Sullivan-sharpened bits are made to exact shape and gauge by tool steel dies and dollies. They "follow" accurately in the drill hole.

With the Sullivan gauging device, genuine double taper bits are quickly and correctly formed, providing increased drilling speed.

Sullivan Furnaces and Sharpeners insure that each steel is of uniform hardness, of exact shape, that the steel quality you paid is preserved and that you will obtain the maximum feet of hole from each steel

Ontario's Minerals

PROVINCE OF ONTARIO

Hon. CHARLES. McCREA, Minister. DEPARTMENT OF MINES *Thos. W. Gibson*

Mineral Areas

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favourable for the occurrence of minerals 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver veins of Cobalt, Gowganda and South Lorrain occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

Economic Minerals

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario: — actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluorspar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, Portland cement, brick and tile, meet every demand.

Mineral Production

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1922 to be worth $62,202,169, of which the metallic production was $38,190,711.

The following figures show the growth of Ontario's mineral industry by five-year periods since 1891 when a Bureau of Mines was first established.

Year.	Value.	Year.	Value.
1891	$4,705,672	1911	$41,976,797
1896	5,235,003	1916	65,303,822
1901	11,831,086	1918 (Maximum war output)	80,308,972
1906	22,388,383	1921	48,128,387

Dividends.

Dividends and bonuses paid to the end of 1922 amounted to $28,096,699 for gold mining companies, and $86,238,185 for silver mining companies or a total of $114,334,884

Mining Regulations

A miner's license costs $5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of $2.50 or $3.00 per acre, depending on location in unsurveyed or surveyed territory.

Assay Office

The Provincial Assays Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario

Publications

For list of publications, illustrated reports, geological maps and mining laws, apply to

Thos. W Gibson,
Deputy Minister of Mines
TORONTO, CANADA

Toil is the Sire of Fame

As builders of Power Transmission Machinery, we have not achieved eminence by accident.

Nearly forty years of patient, progressive effort is represented in the extent of our plant and by the number of our customers.

There's scarcely a big Power Transmission job in Canada that we haven't handled. This accumulated experience makes our Engineering Department a clearing house for ideas on modern plant practice.

If you've a job to lay out that you think we can help you with — come and see us or write us about it. You'll find that we are able and willing to give the best that is in us in order to serve you.

Adding Impetus To The Development of Mining

The development of Canada's enormous natural resources will affect her whole future. Her vast mineral wealth, as yet practically untouched, is to-day attracting world-wide interest from far-seeing investors.

It is appropriate that the Imperial Bank, whose policy has ever been to concentrate exclusively on Canadian affairs, should be powerfully furthering that interest. This Bank, by placing branches at strategic points throughout the mining districts, has materially aided the whole industry.

Those who contemplate becoming connected in any capacity with mining would be well advised to take advantage of this Bank's facilities.

IMPERIAL BANK OF CANADA

Peleg Howland, President. A. E. Phipps, General Manager

Absolute Uniformity in Hercules Oils

Have you had difficulty in finding a flotation oil which conforms exactly to your specifications in every shipment?

Hercules Pine Oils will solve your problems. They are produced under strict chemical control. Uniformity in every lot we send to a customer is the aim of our organization.

We would welcome an opportunity to demonstrate to you the exactness with which we can comply with specifications. We invite correspondence and offer the experience of our technical service men to help you solve any of your flotation problems.

WO OPEN DOORS—AND THE KEY TO ONE

Mr. J. A. Robb, Minister of Immigration at Ot-a, has announced that he will open wide the door nmigrants from Europe, provided they measure up ertain physical and moral standards. The adop- of such a policy will, no doubt, stimulate immi- ion; but how far will it result in filling up the nt places of our land? Numerous writers and kers have pointed out pertinently during recent ths that there is another open door, through h our population is being diminished quite as fast is being increased by immigration.There is virtually restriction on the movement of Canadians to the ted States; in fact our neighbors welcome Cana- ns, for their brain as well as for their brawn. At sent there is an active demand for unskilled labour e, so it is more than likely the new immigrants to ada, or their immediate predecessors, will cross border when they have been here long enough earn the ways of this western world and to become ficient workmen.

Thus has Canada become a training ground for Am- an labour. The opportunities here for earning a d livelihood are not equal to those in the United tes.

t is even more important to keep the population have got than to induce further immigration. Native n Canadians of all classes are likewise lost to Can- in large numbers annually. The last Dominion sus showed an emigration of appalling dimensions, l recent official returns show that the movement tinues unabated. Unless this leak is stopped, the spect of increasing our population materially dur- a reasonable term of years is small indeed.

t is obvious that material prosperity, including re- nerative employment, a high standard of living, l the hundred-and-one incidental features of oom'' times, provide the chief attraction in the ited States. Our problem is to match these attrac- ns in Canada. In numerous instances our natural ractions are the equals of those of our neighbor; but have failed so far to make similarly good use of m. We wish to point out a present opportunity.

A gold boom, if well founded and of large dimen- ns, will attract and hold colonists, industrial work- s and others in numbers quite out of proportion to e numbers actually employed in the mines. It en- ges the markets for everything from potatoes to s, or from cabbages to compressors. If the gold mining industry should be of sufficient dimensions, it might even dominate the national life, as it does in South Africa. Already we have in our north country gold mines whose annual output is one-tenth that of the Rand. Unless all signs fail, the output of the mines at present established will be doubled within four or five years to equal one-fifth of the South African production. If geological reasoning is valid, many new mines will be established along the hundred and fifty miles of gold belt, adding impetus to the boom and giving it further justification.

The gold boom has commenced. If our legislators will continue to aid development during these early stages, as practised always by the authorities in Ontario and as promised recently by Mr. Perrault and his colleagues in Quebec; if public authorities and the public press will combine with private interests to suppress the ''wild-catting'' that has cost us so dear on former occasions; if our mining laws and regulations retain the character of stability, justice and liberality by which they are known at present; if Canadian investors will, by a discreet and well-planned use of their funds at the direction of competent mining men, encourage foreign investors to add their quota; then we may find that, almost before we know it, the tide of prosperity and of immigration will have changed in favour of this land with a golden present and a golden future.

PROPOSED BOUNTY ON IRON ORE

Hon. G. Howard Ferguson's announcement in Sault Ste. Marie last week dealing with Ontario's iron ore problem is an important step in the building up of an iron ore industry in the province. He stated that at the next session of the legislature in Toronto a move will be made to provide the bounty recommended by the committee on iron ore appointed by the late government, adding that he believed the federal government would contribute to this bounty. He also committed himself on this occasion to the appointment of a geologist whose special duty it would be to make a study of the province's iron ore supply.

We are pleased to know that Mr. Ferguson thus endorses the conclusions of the advisory committee, who have searched long and faithfully for a solution of the problem committed to their care. When this committee was appointed sixteen months ago, we pointed to the fact that, since it contained no members qualified by training and experience to pass judg

ment on this problem in its technical aspects, the services of such a specialist should be retained on behalf of the public. The occasion warrants the addition of such an one to the staff of the Department of Mines, and Mr. Ferguson has promised that this shall be done. Later we expressed the opinion that the committee's principal conclusion must concern the practical question of a bounty, and hoped they would recommend it. It is gratifying to know, not only that they have recommended the bounty, but that the Premier backs them.

We are convinced that any reasonable measure that will ensure a supply of native iron ore to the blast-furnaces in Ontario will repay handsomely its expense to the public. Industrial activity in this country is not up to par, and students of affairs tell us that there is a still duller time ahead. The slackness of industry is reflected in a depression in agriculture, progress in settlement is halted, and the exodus to the United States is speeded up. By means of the bonus scheme that is proposed an industry of first-rate dimensions will be created as fast as our factories can turn out the machinery required, employment will be assured directly for some thousands of workers, and the country will be saved a bill of several millions annually for imported iron ore. The cost of this in taxes will be small in comparison with the benefits, and it is considered by competent judges that the total cost will be more than repaid to the country by the time the bounty expires.

It should be borne in mind that the Algoma Steel Corporation have offered definitely to build and operate at the Helen mine in Michipicoten a large plant for calcining and nodulising siderite ore, provided a bounty of adequate dimensions is granted for a term of, say, twelve or fifteen years. The Corporation has, at the cost of several million dollars, proved conclusively the commercial utility of this process, and has likewise blocked out sufficient ore at Helen mine to feed a 1,000-ton plant for a couple of centuries. With the present competition from United States ore, such a plant cannot meet expenses, including interest charges. If the bounty is made sufficient to meet these interest charges and to wipe out the cost of the plant before it expires, the Corporation is prepared to find the capital required, and is willing to trust to favourable developments in the future for its profits. This is a frank and a fair proposal, and we hope to see it taken up within the next few months.

The problem of treating low-grade magnetic ore is not so far advanced as in the case of siderite, but is equally promising. It is here that the aid and advice of an all-round specialist in iron ore will first be required. The experimental work at Moose Mountain has reached an advanced stage, but has not yet reached the position of stability effected in the case of siderite by years of commercial operation at Magpie mine. It may be that the experiment at Babbitt, Minnesota, will supersede the work at Moose Mount We are confident that further concerted and w directed effort will solve the problem of this magn ore in short order.

For progress in the future, we look mainly to iron ore specialist who is to be appointed. As m tioned before in these pages, the various eff wards the establishment of an iron ore industry Ontario have lacked coördination, and hence m effort has been misdirected and wasted. For insta much has been done to suit Canadian ores to Ameri blast-furnaces, but little has been done to develo ferrous metallurgy that will suit our own ores. first duty of the new officer of the Department Mines will be, of course, to unite and to continue present efforts to provide an indigenous ore sup for the present furnaces. But we look forward time when, through the united efforts of all thos terested, a more suitable, a more profitable and a tinctively Canadian method will be found of turn our iron ore into iron and steel.

TRADE WITHIN THE EMPIRE

It is no disrespect to the other Premiers of the Ov seas Dominions to say that General Smuts, the P mier of the Union of South Africa, is easily the standing figure among them. He is marked out that position, not only by his unequalled experience the responsible conduct of public affairs of the magnitude, during the most momentous period modern history, but also by his proven sagacity a capacity, combined with very unusual gifts of thought and concise expression. And, at the open session of the Imperial Economic Conference, he w characteristically, to the core of the inter-Impe trade question and showed along what lines the s tion of that much canvassed problem should be sough

Addressing himself to Sir Philip Lloyd-Grae president of the British Board of Trade, he sa "The assumption of the American debt seems to to be an event which is bound to call for recons tion of many of your old policies. The United St has not only erected a high tariff wall around her fr tiers, and debarred many of our products from go to her, but she now claims, and rightly claims, pay ment of a very large amount of money annually fro this country. The necessity under those circums is forced upon this country to develop the Empire far as possible, to turn its attention to those p of the Empire especially which are capable of gr development, and of producing those articles which great quantity you still take from America. You hav mentioned the matter of cotton. Cotton is a raw ma terial which in the largest quantity we still take fro the United States, but that is not the only raw ma terial which we take from her. She supplies us w

y with cotton, but very largely with copper, and y largely with tobacco. In fact, she has supplied and still continues to supply us with a very large nber of different raw materials which the Empire perfectly capable of producing if properly devel-d."

Premier Smuts had previously sounded emphatically right note in laying stress on the great urgency of uring a settlement in Europe. This is a matter with very direct bearing on the subject of inter-Imperial de. At the best, any outlet Great Britain can find her manufactured products within the Empire will be sufficient for her needs, in the light of the gig-ic task she has undertaken as regards the repayment the debt to the United States. On this head Premier uts spoke words of wisdom. "I fear," he said, "that ess there is a real recovery in the world, unless you succeed in re-establishing the trade and commerce the world, you may find you have undertaken an in-erable burden for this country. Our duty, therefore, o move heaven and earth to have peace re-established Europe." He added that it was a policy of desper-on to suppose that Europe could be left alone in her sent stress. "You cannot have even the possibility of ing the American debt, unless you can restore peace-conditions in Europe."

For our part, we are persuaded that, unless peaceful nditions in Europe are restored, we cannot have that equate extension and expansion of inter-Imperial de for which we are looking. For a really full devel-ment of inter-Imperial trade is, and must necessarily dependent, to a great extent, at any rate, on the toration of conditions approximating to the normal other parts of the world. Any view of the question ich does not have regard to this fact is a very short-hted view.

By this we do not, of course, mean that the fostering trade within the Empire shall be postponed to the toration of conditions approaching the normal else-here. On the contrary, it is absolutely certain that e energetic development of Imperial resources and er-Imperial trade ought to be taken in hand forth-th, and that, if it is so taken in hand, it will be bound, the long run greatly to assist, even though indirectly, e restoration of those other markets, the present limit-on of which is affecting so adversely the purchasing wer of the whole British Empire.

THE OIL WELL AT WAINWRIGHT

The long search for oil on the western plains would pear to have been rewarded at last in well No. 2 of ritish Petroleums Limited. A correspondent who has st inspected this well gives us some particulars. It in Section 30, Township 45, Range 6 West of the 4th eridian, about six miles north of the town of Wain-right, Alberta. The well has come in at a depth of 030 feet with a daily capacity of sixty barrels, from sand seventeen feet thick, to which the name "Cre-lle sand" has been given, in honour of the driller who first struck it. We expect to have further details for announcement in an early issue. Meantime we wish to congratulate those whose faith and pertinacity have resulted thus fortunately, and we trust that further search will reveal there the long sought and well hidden oil field that has eluded so long the geologist and the driller.

A BANKER ON MINING

The Royal Bank of Canada has someone on its staff who has grasped in part the significance of mineral development in relation to the all-round development of our unused resources and of our industrial system. On another page we reproduce the resumé of conditions in northern Ontario and Quebec printed in the Bank's November news letter. Its concluding paragraph points out how important it is that the vast pre-Cambrian area that now separates East and West should become peopled and productive, that Canada may be in fact an economic and social as well as a political unit.

The writer of this article in the Royal Bank's review does not, however, mention some other points that are of equal importance in the future and of much greater importance in the years immediately before us. It has been truly said by students of human affairs and human history that the mining industry is the principal agency of civilization and of material progress. Not only this, but a thriving and expanding mineral industry provides what is probably the greatest possible stimulus to the development of other industries and to the settlement of the land.

This is not merely a matter of history; it is being exemplified today in more than one quarter of the globe. In South Africa industrial progress and agricultural prosperity are directly dependent upon the gold mines of the Rand. This has its counterpart in the fact that the larger part of the Union's public revenue is derived from leases and taxes from the mines. In time the gold deposits will be worked out; but by that time mining of the more prosaic metals and minerals, industry and agriculture will have been developed into a self-supporting unit. In the heart of the continent, far to the north in the Belgian Congo, the first large white community is being settled round the mines and smelters that promise some day to produce a large part of the world's copper. We have referred before in these pages to the part mining development took in opening up Australia and the western United States to settlement.

Our bankers and business men will do well to study this subject in its broadest aspects; it will repay them handsomely to do so. Then it will become the rule, not the exception as it is now, to find that their public utterances and their private transactions touching the mineral industry demonstrate a working acquaintance with its methods and an adequate appreciation of its true worth.

Mining Activities in The Pas Mineral Belt

Progress of Operations During the Season of 1923

By J. A. CAMPBELL*

With the exception of certain years of the war period, when copper production was specially necessary, there has been more actual mining work in The Pas mineral belt during 1923 than in any previous year. Particularly has Herb (or Wekusko) Lake come to the front during this period. The work of developing ore on the Bingo property has continued steadily, twenty-five to thirty men being employed working in three shifts per day. A full equipment of machinery of the latest improved type for this work was taken in and installed in the early months of the year, and was put into operation in May.

Now the main shaft has been sunk to 420 feet and approximately 400 feet of drifting has been done. This work shows the quartz to have increased in volume at depth while the values appear to have been maintained. A recent Government report states:—

"In the free gold showings in the veinstuff, as for instance below the 200-foot level, the gold appears to be associated mainly with the galena, but is very clean, and presumably almost completely free milling."

The satisfactory results being obtained at the Bingo are giving an impetus to mining development in the Herb Lake district generally. Properties such as the Kiski and Northern Manitoba, on which shafts have been sunk and considerable development work done, have been intensively prospected and other gold-bearing veins found. The Wekusko Mines, Limited, a Saskatoon corporation, are actively developing their property at Broad Bay and a shaft is being sunk under contract.

What those interested in this region are looking forward to now is the consummation of a deal whereby active work on the Rex will be resumed at an early date. A shareholders' meeting is announced to take place at Boston shortly to consider a proposal whereby the present interests, hitherto sometimes conflicting, will be turned over to a well-known Canadian mining concern and thereby consolidated. It is on the boards that other nearby properties may subsequently be included with it. The Rex is in good condition for operation but is considered to have been held back through lack of capital and to some extent through lack of co-operation among those interested. In any event, this valuable property cannot much longer remain inactive. Resumption of work thereon, taken in conjunction with that being done on the Bingo, will undoubtedly result in other important developments taking place in this camp.

The withdrawal last fall of a prominent mining company from the Elbow Lake district, where it had an option on the Murray property, was looked upon at the time as a matter of serious import. However, the owners were not discouraged and continued the work of examination, which had hitherto been of a somewhat superficial nature. Their efforts were rewarded when the shaft was sunk to 42 feet by the discovery that the country rock carried considerable gold values. A new organization was formed to handle this property and the work will continue. On the Garbutt zone, farther north, additional prospecting has uncovered a shoot in which there are abundant free gold showings.

Owing to the weakening of the copper market there has been less activity in copper areas than would otherwise have been the case. The Manitoba Metals Mining Company have been diamond-drilling on their Flin Flon properties all summer and Dr. Armstrong with a considerable party has been engaged for the company in work of intensive prospecting in the district. It is reported that a successful season has resulted.

A noteworthy feature in connection with the year's operations is the number of mining engineers who have visited the district and made examinations of properties. Among the companies represented by these are some of the largest and most important in the United States and Canada.

An exceedingly important item from the standpoint of the mining man is the matter of transportaiton facilities. In this respect Herb Lake is now very favourably situated. There is a weekly train service from The Pas to Mile 82 on the Hudson Bay Railway, and from that point to the lake, a distance of eleven miles, is a road built by the provincial government. A road gang has been working steadily on this all summer, draining, grading, gravelling, etc., and the road is now in good condition for traffic. Besides, a reliable telephone service is in operation between The Pas and the mines and intermediate points.

DEVELOPMENT OF NEW HYDRAULIC CLASSIFIER

In the work on ore classification problems in treating complex lead-zinc ores of the Coeur d'Alene and other mining districts of Idaho, an improved type of hydraulic classifier has been developed by A. W. Fairwald, attached to the Moscow, Idaho, field office of the United States Bureau of Mines. It is believed that this new classifier is more efficient than any now in use, and that it represents a distinct advance in metallurgical treatment. The new classifier has been tried out on a commercial scale in one of the mills, with the result that a greatly improved grade of classification is being effected. It is believed that table concentrations will be greatly improved when the tables are fed with well classified material. It also appears that with this type of classification, galena and sphalerite may be separated on tables into marketable products, and that much of the fine grinding and difficult flotation treatment of complex lead-zinc ores may be eliminated.

Intense interest in the trial has been manifested throughout the district, and it is expected that many other mills will install this superior device and thus improve their products and conserve mineral now lost in the reject.

The fact that there is a great lack of knowledge as to the importance of proper classification of ground ore in preparation for table concentration led to the undertaking of these studies by the Bureau of Mines. Many forms of classifiers are in use, but generally there is an altogether mistaken notion as to the grade of work being done by the classifier in use. All sorts of devices are called classifiers and a variety of procedures in practice are called classification. There is no unanimity of opinion among mill men or investigators as to the relative advantages of a natural product feed, a sized product feed, and a classified product feed to concentrating tables. However, fine grinding of the entire mill feed is coming to be looked upon as a procedure leading to difficulties and to loss.

* Commissioner of Northern Manitoba.

Natural Gas and Petroleum Resources of Western Canada

Helium—Its Occurrence, Recovery and Use

By NEWTON W. EMMENS

(Continued from page 920)

Physical Properties of Helium

Helium is the second lightest substance known, is colorless and odorless, has an atomic and molecular weight of 4, and is chemically inert. Its density as compared with air is 0.1368 (that of hydrogen is 0.0696); it weighs 0.0112 pounds per cubic foot (hydrogen weighs 0.0056 pounds per cubic foot) but has a buoyancy in air as compared with hydrogen of 93 per cent. For many years all attempts to liquify it failed, but in 1908 H.K. Onnes, a Frenchman, succeeded. He found that it liquified at a temperature of -451.3 deg. F. (about 8.1 deg. F. above absolute zero), and had a density, in the liquid form, 0.122. It is soluble in water at a temperature of 68 deg. F. to the extent of 1.4 per cent. by volume, but is insoluble in absolute alcohol and benzene. Helium is present in all radio-active minerals and springs and is also present in many rocks that form the earth's crust.

Interesting investigations carried out by Rutherford, Ramsay, Soddy, Boltwood and other scientists go to show that helium is one of the end products, and lead the other, of uranium and that this substance (uranium) may be provisionally considered to be a compound of lead having the formula $PbHe_8$; also that radium is one of the intermediate products produced during the decomposition. Those who are interested in this phase of the subject and want additional information will find it in the "Proceedings" of the Royal Society, Vol. 72, p. 204, 1903, in a paper written by Sir William Ramsay and Frederick Soddy; and in "Science", new series, Vol. 49, p. 1, 1919, in an article by T. W. Richards.

Extraction by Refrigeration

The separation of helium from the other gases with which it is associated in natural gas is accomplished by refrigeration, in which the temperature is reduced to the point where all the constituents of natural gas are liquefied with the exception of helium. The temperature required to accomplish this depends upon the composition of the gas being treated, but it is very low, as may be seen from the following table, which gives the liquefying temperatures of the gases that are met with in natural gas:

Name of gas	Temperature required to liquefy at atmospheric pressure
Methane	—265° Fahr.
Ethane	—135° "
Propane	— 49° "
Butane	+ 34° "
Pentane	+ 97° "
Carbon dioxide	—108° "
Oxygen	—293° "
Nitrogen	—317° "
Hydrogen	—423° "
Helium	—451.3° "

If at the same time the gas is being cooled it is compressed the temperature of its liquefying point is raised.

In order to obtain the low temperatures necessary to liquefy the gas, advantage is taken of the results obtained by Professor W. Thomson (Lord Kelvin) and James Prescott Joule in their experiments in the liquefaction of gases. They found that if a gas under pressure be suddenly expanded there is a great drop in its temperature, the amount of which depends to a great extent upon the difference in pressure between the compressed and expanded gas. This is known as the Joule-Thomson effect.

Linde Process Most Successful

In the Linde process of extracting helium from natural gas advantage is taken of this Joule-Thomson effect. The gas is compressed to about 3,000 pounds per square inch cooled and then expanded through a small orifice in a suitable apparatus to about 300 pounds, thus causing a big drop in temperature. This cold gas is used to cool another lot of compressed gas, which in turn is expanded and brought to a still lower temperature. By repeating this cycle over and over again, as is done in the Linde process, a point is reached when the temperature is reduced to the liquefaction point of the gas being treated, and the condensed portions can be drawn off from the uncondensed. In actual operation of the plant it was found possible to obtain helium of a purity of 70 per cent. on straight runs, and by taking this helium and re-processing it, a final purity of 92 to 95 per cent. was obtained.

The Claude process makes use of the cooling effect obtained by making the compressed gas do work, by causing it to expand in the cylinder of an engine, and making use of the power thus obtained. Although in this Claude cycle the Joules-Thomson effect is made use of, its value is greatly reduced because the initial pressure of the gas is much lower than in the Linde system, the expanding of the gas in the engine being relied upon for the maximum effect. The plant using this process succeeded in producing helium of a purity of 62 to 70 per cent. and this gas was re-processed in the Linde plant, bringing it up to a purity of 93 p.c.

The Norton process makes greater use of the cooling effect by making the gas do work in multiple-expansion engines and uses a lower initial pressure than either of the other systems, utilizing much of the power thus generated in operating the plant. Norton also used a new type of heat interchanger and fractionating still. Because the power requirements for gas compression are so much less in the Norton plant than in either of the other two, it was thought this system would prove to be the most efficient and would produce helium at the least cost. Such, however, does not appear to be the case; it has been found in the three plants mentioned that the Linde process gave the best results.

In August 1918 the Army and Navy Departments of the United States realized the great importance of having ample supplies of helium for military purposes, and as it had been proved by the experimental plants that its recovery from natural gas was practical on a large scale, it was decided to erect a much larger plant using the Linde process that would have a production of 30,000 to 40,000 cubic feet of helium per day. The construction of this plant was commenced, at Fort Worth, Texas, in October 1918 and it was

completed in December 1920. This plant has produced over 2,000,000 cubic feet of helium of a purity of about 95 per cent. It is the gas from this plant that, together with the small amount made in the experimental plants, was used to inflate the gas bags in the U. S. dirigible ZR-1.

Re-Purification of Gas

After helium has been used in a balloon or dirigible for some time, it becomes contaminated with air by interchange through the fabric of the gas bags, and when the grade of the gas becomes reduced to 85 per cent. its buoyancy is too low to be of practical use and it must be refined. After refining, it can be again used for aeronautic purposes. To provide for this, a re-purification plant has been built at Langley Field, Va., and another is in course of erection at Lakehurst, N. J. The process used in the re-purification of the gas consists of subjecting it to the temperature of liquid air, while under pressure, which condenses any nitrogen and oxygen with which it may be contaminated and allows the helium to pass out of the apparatus at its original purity of 95 per cent.

In addition to these two plants, another, smaller one has been built and mounted on railway cars so that it can be taken to any point in the country on a railway where it may be needed. In this plant the compressed gas to be purified is compressed and passed through cocoanut charcoal at a low temperature. It has been found that this charcoal has the property of absorbing oxygen and hydrogen at low temperatures, but does not absorb helium. It has also been found that the degree of purification obtainable by this method is greater than in the Linde or other processes, it is possible to get a purity of over 99 per cent helium.

Helium Occurs in Nitrogen-Rich Gas

The helium-bearing gas being treated in the United States plants mentioned is obtained from the Petrolia natural gas field, in the northern part of Clay County, Texas and has an average helium content of 0.95 per cent. The wells are not deep and the producing sands are found from 1,550 to 1,750 feet below the surface. They occur at the base of the formations of Permian age, and of the upper Pennsylvanian (Carboniferous) age of the Palaeozoic epoch. The gas from this field is also high in nitrogen content and has a low heating value, as will be seen from the following two analyses:

	No. 1	No. 2
Carbon dioxide	0.0	0.2 percent
Methane	48.4	52.7 "
Ethane	12.8	9.3 "
Nitrogen including Helium	38.6	37.8 "
B.t.u. per cubic foot	755	734

Sample No. 1 came from the Matlock No. 1 well and was analyzed by the U. S. Bureau of Mines, Sample No. 2 was from the No. 1 Beatty well and was analyzed by the Lone Star Gas Co. Both analyses are taken from Professional Paper 121, issued by the Geological Survey of the United States.

In the investigations into the helium-bearing natural gas resources of the United States and Canada, carried out by both Government Departments and by private persons, a great deal of valuable data has been obtained and it has been found that it is only those gases containing an appreciable proportion of nitrogen, and of low heating value, that contain sufficient helium to make its extraction practical on a commercial scale. But it does not always follow that those wells that produce gas consisting almost wholly of nitrogen also contain large percentages of helium, as will be seen from the following analyses taken from publications issued by the Canadian and United States Governments.

Gas Field	Nitrogen content percent	Helium content percent
Morrison, Okla	25.0	0.22
Ponca City, Okla	40.1	0.36
Billings, Okla	42.5	0.39
Loco, Okla	16.2	0.17
Otto, Kansas	57.8	1.04
Dexter, Kansas	82.7	1.84
Augusta, Kansas	88.0	2.00
Sedan, Kansas	55.7	1.94
Fredonia, Kansas	16.4	0.62
New Albany, Kansas	9.8	0.49
Petrolia, Texas	37.4	0.96
Vinton Co., Ohio	15.1	0.43
Vinton Co., Ohio	9.6	0.40
Barnwell, Alberta	6.8	0.36
Bow Island, Alb. (C.P.R. wells)	11.2	0.30
Stony Creek, New Brunswick	12.2	0.06
Selkirk-Dunnville, Ont.	8.3	0.27
Brant-Onondaga, Ont.	11.0	0.30
Blackheath-Seneca, Ont.	8.0	0.32

Geological Occurrence

It has also been found that the richer gases occur only in the upper part of the Pennsylvania (Carboniferous) formation and at relatively shallow depths below the surface. The helium-bearing gas from the Vinton, Ohio, fields comes from the Clinton and Medina sands of the Silurian formation, as does that of the Ontario fields. The helium-bearing gas of Alberta comes from the sands that occur in the Belly river, Niobrara, Benton and Dakota strata of the Cretaceous system. In the United States at Havre, Montana, a well produces gas from the Cretaceous formation containing 0.27 per cent helium; at Minot, North Dakota from the same geological horizon there is some gas containing 0.17 per cent. helium; but in other parts of the country the Cretaceous gas does not contain over 0.09 per cent. and in most cases it is only present as a trace. The gas from the California fields is derived mainly from sands occurring in Tertiary strata and does not contain any helium except in three wells, one in the Coalinga field that showed a content of 0.11 per cent., one in the Santa Maria field that contained 0.13 per cent. and one in the Fillmore field that showed a content of 0.31 per cent. This last was a "dry" gas and came from a sand at a depth of only 600 feet. The gas from the Louisiana fields is derived from strata of the Cretaceous and Tertiary systems, the maximum amount of helium contained in the former being less than 0.08 per cent. and in the latter not more than a trace. In Wyoming one well producing gas from a sand in the Carboniferous formation showed a helium content of 0.26 per cent while those deriving their gas from the Cretaceous strata show only traces or none at all.

From the results of the work done in the United States it may be stated that helium in quantities in excess of 0.5 per cent occurs only in nitrogen-rich natural gas derived from Carboniferous strata at shallow depth, and that when such strata are deeply

the percentage of helium contained in the gas ses. In Ohio, gas derived from the Upper Silu- trata contains around 0.4 per cent and in a cer- ield in the west, gas from strata of the Creta- period contains upto 0.27 per cent helium. In la, however, gases from the Cretaceous contain h as 0.36 per cent helium, and it is to this gas ve must look for a supply of that very valuable nt, particularly in view of the fact that this is ly source so far discovered within the Empire.

Canada's Helium Supply

a very interesting paper read before the Ameri- nstitute of Mining and Metallurgical Engineers ir recent meeting in Montreal, Dr. R. B. Moore the following statement: "As this country (the d States) has the only large source of natural ontaining helium in the world, it is of great im- nce, from the national defence standpoint, that nonopoly be retained; therefore, the exportation elium is inadvisable. The matter should be led without great difficulty as there are no com- ial plants in operation at the present time and, fore, the control of helium does not interfere capital already invested." In this statement Dr. e refers to gas containing 0.5 per cent. and over elium, because he states that gas containing less that amount is not considered of commercial e.

hile we do not possess within the Empire, so far known, at present, any sources of helium-bear- natural gas as rich as some in the United States, have large volumes containing between 0.30 and per cent and it is quite practicable to separate bring it up to a purity of 99 per cent, and to store steel cylinders against the time when it may be led for aeronautic purposes in defence of the coun- or for commerce. There is no question but that um from the rich gases in the United States can be duced much more cheaply per thousand cubic feet from the lower grade Canadian gases; but cost is everything when it comes to defeating the enemy. re is absolutely no question that the country com- ding adequate supplies of helium in the next war have an advantage that cannot be estimated in ney, and it might easily make all the difference ween victory and defeat. If the Germans had been e to fill their Zeppelins with helium instead of with drogen during the recent war, there would have n a very different tale to tell.

Canadian Helium Now Being Wasted

The United States is so fully alive to this that there s been introduced a bill in Congress looking to the nservation, production and exploitation of helium f national defence and for the development of com- rcial aeronautics, and they have built a plant which producing helium on a fairly large scale, — the ly plant of its kind in existence. The Canadian overnment also realizes the importance of this mat- r, as is proved by their reserving to the Crown all lium contained in natural gas and the right to ex- act the same; but so far no effort is being made to t the reservation and right into effect, and every y the store of helium is growing less and less by me 20,000 cubic feet, which is the quantity con- ined in the natural gas consumed daily in western nada.

Those of the Journal's readers who are interested the scientific side of this most interesting element, helium, will enjoy reading Professional Paper 121, issued by the Department of the Interior of the United States, entitled "Helium-Bearing Natural Gas," written by the late G. Sherburne Rogers, and Bulletin No. 31, of the Mines Branch, Ottawa, on "Some Sources of Helium in the British Empire," by Dr. J. C. McLennan and associates.

PERSONAL AND GENERAL

Mr. Sherwin F. Kelly, who is the exponent on this continent of the Schlumberger method of electrical prospecting, is now an assistant on the staff of the department of geology of Toronto University. Last summer he conducted electrical surveys of some deposits in the gold belt of northwestern Quebec, whose further examination by diamond-drilling should give some very interesting comparative data.

Mr. L. H. Cole has returned to Ottawa after a fruitful season spent in investigating the alkali deposits of Saskatchewan on behalf of the Mines Branch. He has a comprehensive report on this subject in course of preparation.

Mr. Howells Fréchette, chief of the ceramics division of the Mines Branch, Ottawa, is on a tour of the west with a view primarily to completing the store of materials for the Canadian ceramic exhibit at the British Empire Exhibition.

Mr. J. J. Warren, president of Consolidated M. & S. Co., has returned to Trail for a few weeks.

Directors of Dome Mines paid a visit to their mine in Porcupine last week.

Mr. R. B. Watson, general manager of Nipissing, is in Toronto General Hospital, where he is recovering from a threatened attack of pneumonia.

Mr. Harrison; E. Clement, Manager of the Crystal Copper Company of Butte, Montana, has been appointed general manager of the Premier Paymaster Mine and the United Mineral Lands Companies in Porcupine. The resident manager will be Mr. W. G. Norrie-Lowenthal, of British Columbia.

Mr. Hamilton B. Wills is understood to be making a satisfactory recovery from a cerebral hemorrhage, from which he suffered a short time ago.

Mr. R. A. Bryce, of Toronto, has returned from a few days' trip to New York.

CENTRIFUGAL CONCENTRATION

In connection with experimental work performed some time ago at the Reno, Nevada, station of the United States Bureau of Mines, on the concentration of a zinc descloizite ore carrying vanadium a laboratory size centrifugal concentrating bowl was developed for extracting metals from the slimes that represented the major portion of losses in the table concentration of the descloizite ore. More recent experiments indicate that the bureau's concentrator may have a commercial application to a neglected field of metallurgy, the concentration of slimes that are not amenable to flotation, or that it may possibly compete with flotation itself in the treatment of some ores. Improvements evolved have been incorporated in a design for a small commercial machine with which further [illegible] may be conducted under plant conditions.

YUKON WIRELESS STATIONS

The Gold Commissioner of Yukon Territory has reported officially that the new radio stations at Dawson and Mayo are working spendidly. These two stations constitute the first link in the projected Dawson Edmonton wireless system

An Iron and Steel Industry for British Columbia

Supplementary Report by Victoria Chamber of Commerce

A special committee was appointed recently by the Victoria Chamber of Commerce to investigate the proposals of Coast Range Steel Ltd., for the establishment of an iron and steel industry in British Columbia. The first report of this committee already has been published. (C. M. J.—October 5th, 1923). It was a condemnation of the suggestion that the provincial government should guarantee the bonds of the corporation up to $4,000,000. The committee now has issued a supplementary report, which has been considered necessary because of a subsequent interview with Mr. H. J. Landahl, the promoter of Coast Range Steel, Ltd. The conclusions, reached in the first instance, however, have not been altered. They are as decisive, perhaps more so, as those set out in the original document. The last report is brief and to the point. It follows in full:

"Your committee desire to supplement their original report on the Coast Range Steel Company in view of the interview we have since had with Mr. Landahl and his associates.

"We find that whilst the original financial structure was as indicated, it has since been changed in the following manner:

"The proposed cost of the industry is to be twelve million dollars, the entire funds for which are to be provided by bond issue up to 100% of its cost. Four million dollars of this is to be provided by the Provincial Government, four million by the British Department of Industries, and four million by the British Iron Masters, whose status we understand is that of suppliers of the machinery and equipment for the plant, conditional upon the machinery and equipment being purchased in Great Britain. In addition it is proposed to issue a further sum of three million dollars worth of debentures, over and above the twelve million dollars subscribed for by the respective governments as mentioned above.

"The Coast Range Steel Company is capitalized for fifteen million dollars of common stock, which Mr. Landahl states he is prepared to put in the hands of the Provincial Government. Under ordinary conditions this stock would, of course, control the operation of the company, but, in view of the fact that the Provincial and Imperial authorities would be providing all the funds proposed to be expended, this common stock has no value and should in no way control the operation of the company.

"In the case of failure, the property would pass into the hands of the bond holders, and our Provincial Government would hold a minority interest only. There would be nothing to prevent the majority bond holders in Great Britain disposing of this plant in such a case under conditions disastrous to this Province, unless our Provincial Government were prepared to purchase a large portion of the bonds held by the majority holders.

"We submit that, however, faulty and ill-advised in the interests of this province the financial structure may be, it is entirely subsidiary to the major factor of raw materials, cost of production and market available.

"From all the facts we can gather from estimates as to a suitable coke and the cost of it on the Coast, their estimate is more than wide of the mark. They estimate that the composite price of iron and steel was only $41.77 against a recent composite Pittsburg price of $60.60 per ton, or approximately $90.00 laid down in British Columbia. Again, they estimate the total value of iron and s imports into British Columbia to be $8,136,445, of w 90% is from the United States and includes such it as machinery, vehicles (including automobiles) etc., of which total we find only $3,441,136 comprising ma ials which a complete iron and steel plant could prod

"Mr. Landhahl states that there is 337 tons of pig brought into the Coast per day. It is not clearly defi to what territory this tonnage is distributed; but we po out that the official Government figures show that th was imported into British Columbia, during the fiscal y ending March 31, 1923, a total of 2,000 tons of pig i or an average of less than seven tons per day. Mr. Lan ahl's tonnage of 649 tons of iron and steel brought i this Province from foreign countries is, apparently, a rived at by taking the low composite price of $41 (which we have already shown to be less than half t actual composite ton price laid down in British Columbi and dividing it into the entire imports of $8,136,445 f the year ending March 31, 1923, which total sum includ many high-priced articles such as farm implements a machinery, firearms, hardware, general machine stamped and coated products, tools, vehicles (includi automobiles), etc., none of which could be expected to b manufactured by the plant Mr. Landahl has in conten plation.

"We should not, however, lose sight of the fact that, pig iron and steel billets were produced in British Colum bia at a low enough price, the demand for these produc would rapidly increase both within the Province and ou side. We do not agree with Mr. Landahl's statement tha they had to have Provincial Government backing to pro tect themselves against the dumping into this country b foreign competitors, because, in our opinion, the ant dumping regulations are sufficient protection.

"In view of the inaccuracies as to the general condition surrounding the industry as placed before us by Mr Landahl, and, having carefully reviewed the whole sub ject, this committee feels that they cannot change their attitude towards Mr. Landahl's proposal, as shown in the report already presented to you.

"Generally we find ourselves opposed to the commit ment of the Province to a scheme of this magnitude, be lieving that to attempt to commence this industry on such a scale as to immediately challenge ruthless competition from established iron centres, would be unwise and court ing disaster. We have already stated our view that this industry should be commenced on a moderate scale from an experimental standpoint, either as a governmental work or by private enterprise assisted by a bonus, in order to demonstrate beyond peradventure the practicability of the industry at this time.

"All of which is respectfully submitted: F. A. Pauline Chairman; C. P. Hill, R. R. Nield, C. P. W. Schwengers M. P. Plair, Captain Matheson, M. B. Jackson, J. Hinch cliffe, J. B. Clearihue, G. B. Mitchell, E. Tomlin

In view of the position taken by the committee, it would appear to be proper that the comments made by Mr. F. A. Pauline, M. P. P., chairman, in submitting the report on behalf of his fellow investigators should be given. He said:

"It is not a pleasant duty to report unfavorably on a proposal such as Mr. Lanahl's, particularly at this time, when we were all keen to see a greater industrial development. We believe in the iron resources of the Province,

l are confident that they are destined to be an impor-
t factor in our industrial life in the near future. But
regard it as essential that the initiation of this great
ic industry, whether assisted by the Government or
, shall be projected upon such prudent and scientific
es as will give the industry a fair chance for success
m the beginning."

NING IN NORTHERN ONTARIO AND QUEBEC

Under the above caption, the Royal Bank of nada discusses the mining industry in its new letter November 1st. as follows:

Judging from the highly gratifying reports which ıbody the findings of recent geological investiga-ın and from current expansion of mineral output, e mining industry, and principally that of Northern ıtario and possibly Quebec, is rapidly assuming a ore important place in our economic development. ıring the past generation, the output of Canadian ines has risen in value from about $10,000,000 to proximately $220,000,00 having doubled during e last decade alone. In the first six months of this ar, the total mineral production of the Dominion nounted to $87,152,248 in comparison with $60,361,-)9 for the same period last year — an increase of per cent. It is to be noted that Northern Ontario ayed an important role in this increase, the output nickel and copper having expanded materially.

It is, however, in the mining of gold and silver that ıe most notable expansion has taken place. In the ıse of gold the power shortage somewhat handi-ıpped the industry, and it was not until recently that hough power was obtained to provide for capaci-operations of the Porcupine mines. As it as, however, the production during the first six ıonths of the year, almost equalled the high record et during the same period of 1922. Fortunately, ıe power problem has been solved. New equipment as been added and with new producers entering the ield, the year's output will probably exceed the high ield of 1922. During the first six months of the ear, Ontario produced 78% of the entire Canadian utput of gold. Activities during that period in the Porcupine and Kirkland Lake areas were very pro-ounced and production records were steadily increa-ed. The more investigation that is made in this area y responsible authorities, the more optimistic are the eports. Apparently the ore bodies in these fields xtend to very great depth. Across the Quebec bor-ler, certain of the important veins are being inves-igated and it is estimated that gold may extend con-iderably farther east than is now known. The pro-luction of silver also is reviving very noticeably in he northern districts. The South Lorrain tract is he scene of very great activity and continues to con-ribute large amounts to the total output of silver. It is now an established fact that the area surround-ng the lower end of Hudson's Bay and extending even beyond the lakes, known as the pre-Cambrian or Laurentian shield, offers tremendous possibilities for expansion. As yet this area has been exploited only in a very small way.

The facts and figures cited above have two impor-tant implications. They emphasize, in the first place, the tremenous future possibilities of the mining in dustry of Northern Ontario and Quebec from a purely industrial standpoint, and they indicate, secondly, that this industrial development may have a very impor-tant bearing upon the growth and solidarity of the Dominion. Economic progress has been retarded in Canada by virtue of the expansive and largely unex-ploited gap which stretches south of Hudson's Bay for some distance and east and west for a much great-er distance, and which makes a distinct cleavage be-ween eastern and western Canada. This area has presented very serious problems in transportation and in the distribution of goods, and its gradual utilization and settlement may easily have far-reaching signif icance in future development of the country.

RECONSTRUCTION AT LENS

The progress of reconstruction in the mines of Lens, France, is a subject that will interest many Canadian mining men. Last spring, M. Cuvelette, general manager of the Mines de Lens, delivered an address before a conference in Paris that gives a vivid picture of the destruction and the progress of restoration.

It is well known that, even before bombardment reduced the surface equipment of the mines and coke ovens to piles of debris, the Germans had systematically removed what machinery they wanted and had destroyed the remainder.

Subsequent examination has showed the pains they took in flooding the mines. They brought engineers from the Ruhr mines, where the formations are the same, and under their direction the shaft linings were breached with dynamite at points where water-bearing strata were known to exist.

The inflow of water to the damaged shafts through these water-bearing strata was stopped with cement. Nine or ten holes were drilled in a circle at a distance of 40 feet from the centre of the shaft down to these strata. Cement grout was then pumped down, which spread into the crevices, as much as twelve to fifteen tons being thus placed from one bore-hole. This was repeated with an inner circle of holes with a radius of about 30 feet. In some cases this sealed the strata completely, and in others it obstructed the flow of water sufficiently to allow the huge electric pumps to overcome it. This cementing is not effective in sand, clay or chalk, but the flow of water from these strata has been more than matched in some cases by the powerful pumps.

Cementing, clearing away of debris and other preliminaries consumed about two years after the armistice. Since November 1920 most of the pits have been cleared of water, fourteen of them being cemented. But this is only part of the work of reconstruction. Of the 8,000 houses owned by the company, only 33 could be repaired. Now there are 6,000 new dwellings. Some of the coke ovens have been rebuilt, as well as others of the plants essential to a great colliery district. This one company has 23 hoisting shafts and 12 ventilating shafts. The[illegible] clear of water, but the underground workings will not be completely cleared until the end of this year.

REFRACTORIES FOR STEEL MAKING

A survey of operating conditions [illegible] hearth steel practice will be made [illegible] periment station of the United States [illegible] Columbus, Ohio, for the purpose of determining [illegible] in available commercial refractories fall short of giving ideal service. The Bureau of Mines plans later, in co-operation with the steel industry, to undertake the development of ideal refractories for specific services.

Don't be afraid of being too kind. In this world one must be a little too kind to be kind enough.

Geology and Ore Deposits of Rice Lake, Manitoba

Abstracted from a Report by J. F. Wright, Geological Survey of Canada

The following is abstracted from a report by J. F. Wright in *Summary Report,* 1922, *Part C.* of the Geological Survey. The report is accompanied by a preliminary map on a scale of a mile to the inch.

Most of the field season of 1922 was spent in detailed geological mapping of Rice Lake map-area, in southeastern Manitoba. The map-area is part of a mineralized belt of country about 15 miles wide that extends northwestward from about mileage 90 on the Manitoba-Ontario boundary to lake Winnipeg, a distance of about 60 miles. Quartz veins that contain free gold have been known in this belt for a number of years. The Gabrielle claim north of Rice lake was the first claim in this district, and was staked in March, 1911. Since then about twenty-five hundred claims have been staked and up to the end of 1922 over two hundred claims were surveyed. A general reconnaissance survey of the whole mineralized belt was made by the Geological Survey in 1912, and detailed studies of small areas were made in 1916, 1917, and 1921. The field work here described was undertaken to ascertain more definitely the origin and geological relationships of the mineral deposits in this map-area and to provide prospectors with a fairly detailed map showing the distribution of the various rock formations, especially the areas most favourable for prospecting.

Rocks of the Area

As far as known the oldest rocks are a thick series of lavas, ranging from basic to acidic in composition, a part of which was probably extended on land and a part under water. Interbedded with these lavas are thin beds of clastic sediments.

Apparently conformably above the acid lavas is a series of schists and gneisses, a large part of which is probably of sedimentary origin.

These lavas and sediments nearly everywhere stand vertically or at high angles.

East of Rice lake there is a thick series of clastic sediments, which in every noted case strikes about east and west and dips from 30 to 60 degrees to the north. The relation of this series to either the lavas or probable sediments is not known, and it is probable that in the Rice Lake map-area this series is faulted into its present position and its true stratigraphic relations are not revealed, although one outcrop near the east end of Rice lake shows this sedimentary series to be conformably overlain by rhyolite and basalt described under the volcanic group.

A granitic intrusive, porphyry, and diabase dykes cut all three of the above groups of rocks.

Gold Quartz Deposits

Gold deposits are the only known deposits of possible economic value in Rice Lake mining district, though nickel-copper deposits occur, not far to the south, at Oiseau and Maskwa rivers. Gold claims have been staked since 1912, and each year some development work and prospecting are done, but up to the present only a few thousand dollars worth of bullion has been produced, though hundreds of thousands of dollars have been spent. In most cases the development work has not been systematic. Only shallow shafts have been sunk on a great many claims, so that there is little or no information about the extent and character underground of any of the deposits. The Selkirk Gold Mining Company, Inc., is making a systematic attempt to explore the deposits on the Luleo group of claims underground and the results are fairly encouraging. However, a number of the gold-bearing deposits are known to be large enough to encourage further development, if their average values were not so disappointingly small.

The gold quartz deposits outcrop as a series of lenses which partly replace the country rock and fill fracture planes in the volcanic and interbedded sedimentary group and in the granitic intrusives. These fracture or shear zones as already described, are characterized by frequent pinches and swells along their entire length and are only partly replaced with quartz, various sulphides, and gold. The quartz and sulphides in some places display a banded or ribbon structure. In general character and mineralogy these deposits resemble gold quartz deposits formed under conditions of intermediate depth and temperature.

All the known deposits of the area have many features in common, and they will, therefore, be described in groups named after lakes or important mineral claims. De Lury used this system and has given much information concerning the various prospects. The following descriptions necessarily repeat many of the facts stated by De Lury, but all the information available since 1920 is added. No attempt is made to describe in detail the quartz leads on each claim, but rather to describe the important known deposits and general character of the whole group. The claims north of Wanipigow lake and river will be described first because developing and prospecting were active during the summer of 1922.

Luleo Group

This group is in the northwest corner of township 2[illegible] about 6 miles west of Wanipigow lake and 1 1-2 miles north of Wanipigow river. The group covers about [illegible] square miles and includes thirty-five surveyed claims. The outcropping rocks are massive granite porphyry and granodiorite cut by diabase dykes, and contain many schist inclusions. The outcrops occur as low ridges and islands in the spruce swamps and muskegs which are abundant.

Prospectors have sunk many shallow pits along the shears and fractures on the various claims of this group. The Selkirk Gold Mining Company, Inc., have, at the Selkirk mine, sunk 325 feet near the footwall of the main shear of the Luleo No. 2 mineral claim, L. 42--174. At the 125-foot level a crosscut was driven 50 feet to the north, 17 feet in granodiorite and 33 feet in sheared granodiorite and vein quartz. From where this crosscut intersects the footwall of the shear zone a drift was run along the vein 225 feet east and 250 feet west. At 125 feet east the vein was 62 feet wide, but was mineralized only 4 or 5 feet from the footwall. At 200 feet east the vein was almost entirely replaced by schist impregnated with quartz. At the east end of the drift there is very little quartz, but the granitic rocks are badly schisted. Along the west drift the quartz ends where a quartz-mica schist inclusion was encountered. Along the crosscut from the 325-foot level the fracture or shear zone is about 5 feed wide and contains little or no quartz, but along the east drift the sheared zone widens, and quartz is fairly abundant. The above description illustrates the irregular character both of the fracture zones and of the quartz.

In the workings of the Selkirk mine, described above, quartz is the principal gangue mineral and occurs as lenses of either a white, sugary, or a dark, glassy variety. Some of the quartz along the Selkirk mine workings contains no

sulphides, but in a considerable part small grains of pyrite are distributed. In some parts of the vein, especially along the footwall, pyrite is abundant, and associated with it are small amounts of chalcopyrite, arsenopyrite, sphalerite, and galena. The quartz, pyrite, arsenopyrite, and chalcopyrite were evidently deposited contemporaneously, and later were badly fractured, for they are now veined with white mica, calcite, ankerite, quartz, and specks of gold. The granulated sulphides and quartz recrystallized, and in some polished surfaces quartz appears to replace pyrite and in others pyrite replaces quartz. Assays of sulphides with little quartz are reported to run from $150 to $200 a ton. The gold must be finely intergrown with the sulphide because no gold was seen in polished sections. However, specks of gold were noted in the vein material which cuts the sulphide, especially the arsenopyrite. This gold was probably liberated from the sulphide during crushing. Free gold also occurs throughout the white quartz or as thin films along cracks in this quartz. Molybdenite and mariposite (green chrome mica) were noted at one place along the workings. No tourmaline, pyrrhotite, specularite, or other high temperature minerals were noted in this mine or in any of the veins in the map-area. The mineralogy of the gold quartz veins of the Rice Lake mining district is similar to that of Kirkland Lake gold area, Ontario.

Last year the Selkirk Gold Mining Company, Inc., blocked out a considerable tonnage of ore said to assay from $10 to $15 a ton. Beyond this there is little information about the tonnage and value of the ore in any of the claims of this group.

Gold Lake Group

This group of mineral claims is near the centre of the western part of township 23, and includes the claims between Gold and Big Clearwater lakes. Of all the prospects in the Rice Lake map-area the Gold Pan is the best known, and has furnished very rich specimens.

The Gold Seal, Gold Pan, and Gold Pan Extension workings are along the same fracture zone. This zone strikes north 30 degrees west and was traced fairly continuously for 2,500 feet. It varies greatly in width, averaging possibly 2 1-2 feet for this distance. The quartz is very irregularly distributed, varying from 1 inch to 2 or 3 feet in width but averaging less than 1 foot. On the Gold Pan about 725 feet of underground work was done at various intervals between 1916 and 1920. The shaft was sunk where the fracture zone crossed the diabase dyke, and all the rich specimens were found along the western face of the dyke. The open spaces resulting from the fracturing of the competent and brittle diabase evidently made favourable conditions for the concentration and deposition of the gold quartz solutions. In September the Gold Pan workings were pumped out preliminary to stoping the remainder of the rich ore between the 100 and 200-foot levels. Several hundred feet of underground development has been done on the Gold Pan Extension and Gold Seal and the results, combined with the results of the Gold Pan work, show that these deposits underground are very similar in shape and mineral content to their surface outcrops.

To the southwest of the Gold Pan zone a well-developed and continuous shear zone crosses the Pilot, Smuggler, and Canadian Girl claims. The sheared zone is in places over 30 feet wide, but along the strike to the southeast the quartz is not so abundant, which is the reverse of conditions along the Moose shear zone. However, from surface showings this gold quartz deposit is the largest known in Rice Lake map-area and seems to warrant further development combined with systematic sampling and assaying to prove the value of the ore.

Summary

Enough work has been done in Rice Lake map-area to prove that there are large tonnages of minable quartz along a few of the sheared zones, but the average value is too low to make these deposits of economic value under present conditions. Stripping on a large number of mineral claims proves that other quartz veins exposed are too small and irregular in shape to be worked economically, even though they be exceptionally rich. A very noticeable feature about deposits in the granitic intrusives is a marked concentration of high-grade gold ore around the ends of inclusions along the shear zones; as these inclusions evidently controlled the location and continuity of some of the shears in the granitic rocks, future mining will probably prove that the size of such deposits is largely controlled by the size of the inclusion. Underground development indicates that in some cases the outcrops give a fair indication of extent and values in depth. Since the outcrops of the sheared zones are lens-shaped, and the gold-bearing quartz in the shears is very irregular in shape and distribution, a great deal of expensive exploratory work, combined with systematic assaying, must be done to prove the shape, size, and value of each property.

PROSPECTING DE LUXE!

The *Canadian Mining Journal* learned some weeks ago of an unmitigated hoax perpetrated upon strangers in the name of prospecting. It has therefore asked a correspondent to whom all the facts are known to state the case briefly, with a view to preventing its recurrence. This correspondent says:

The London *Times* of March 13th last had the following personal on the front page: "Explorer and Geologist invites Gentleman to complete pioneer ex- "pedition, Northern Ontario (Goldfields); three "others; great opportunity right man; sailing April; "£300 capital and good health essential; highest cre- "dentials. Write Box Y 482, The Times, E.C. 4."

The reply to this put Mr. Dudley Hunt, ex-naval officer, ambitious to make his way in the world, in personal communication with one Horace Laycock, who in 1909 was a solicitor's clerk in Elk Lake during the time of the silver rush into that district. Laycock explained to the enquirer that his brother William Laycock was the explorer and geologist in question and that he, Horace, was acting on his distinguished brother's behalf, enumerating the following points:

First. — William has had four year's personal experience of the territory.

Secondly. — William is a mine owner in Northern Ontario.

Thirdly. — William has obtained information from "official" sources as to the country it is proposed to prospect.

Fourthly. — William made a rapid journey through the district just before winter set in to verify information.

Fifthly. — William thinks so well of it that he is going to suspend his other important interests for six months to get in first.

Sixthly. — William is a wonderful "bushman" and knows the country probably better than anyone else and wants only real "he" men in the party.

The expedition gathered at Elk Lake on May 5th last. In addition to the Explorer, Mine Owner, Geologist, and Mining Engineer, William Arthur Laycock,

three others were in the party; two young Hollanders named Prinz and Van Hien and our friend Dudley Hunt. All were strongly impressed by the "leader" to keep secret the destination of the expedition, as some of the keen prospectors might track them. The residence of the eminent Geologist, Mine Owner, Explorer and Mining Engineer, at Elk Lake, was a two-roomed shack with a lean-to kitchen rather sparsely furnished; but, of course, explorers are obliged to put up with all kinds of hardships.

The expedition, after ten days' delay, started up the Montreal River, and on the second day camped in the wilds at Moyneur's restaurant, later safely reaching Steve Lafricain's outpost, and found the Indians peaceably disposed. The party went into camp around High Falls and the explorer tried to find Powell Creek, but failed, and the expedition prepared to send out scouting parties. By the end of the month a bush fire approached the camp and Billy Shields, a well-known prospector, warned the party; but when the fire came they had just time to cut the tent ropes, jump into the canoes with their personal baggage and depart, the camp and supplies being lost. The party followed Shields to High Falls and got out of the path of the fire.

The lost supplies were replaced by the end of the first week in June and the party loitered around the canoe route in Powell and Argyle, not doing much of anything and looking to the leader to make good. According to the members of the expedition the leader seemed lost and did not get anywhere without first going to find the route, and at last about the middle of the month of June the three, who had already put up $700.00 apiece (first half of the premium), held a council-of-war and insisted that Laycock take them to where he had panned gold in his rush trip the fall before. This locality never turned up, but later the party staked claims on an outcrop of "bull quartz" in Argyle. On the 18th June, the camp got on fire again but most of the stuff was saved.

By this time Prinz was completely "fed up" with the affair and went to Toronto where he consulted a firm of solicitors, who advised him not to pay over any more money and to claim back what he had paid.

The others were inclined to follow Prinz' example, but after considerable acrimonious discussion, and Laycock's promise of improvement in the conduct of affairs, and some persuasion by Laycock's solicitor, those remaining made a new deal and the second payment of $700 each was made by Hunt and Van Hien in Cobalt.

While the expedition was out at Cobalt and other places, they had cached the major part of their supplies, clothing, blankets, cured meats, etc., under the direction of the Explorer, in a pit they dug on an island. A party of fire rangers happened to land on the island to make camp and finally found the cache by the smell, the pit having filled with water and spoiled everything spoilable. The fire rangers hung up the blankets and clothing, but they were almost past redemption.

After the second payment was made by Hunt and Van Hien, the expedition made another start from Elk Lake, but the Leader developed sickness and complained of pains, etc., and Hunt went back to Elk Lake with him and the expedition was left without its Guide, Leader, Geologist, etc., till the middle of July.

During all this time there had been a gold rush into McNeil township, but Laycock had refused to go there although it was only four or five miles from the Thesaurus Mine on the North Bend of the Montreal River, and the next township to Argyle where the party had been loitering for weeks doing nothing useful.

Later Van Hien arranged to leave the party for a few days and go up to Jim Nelson's (Thesaurus Mine) and while there one of the prospectors named Jim Byrnes took him in to McNeil and helped him to stake a claim in the gold formation there, which may be of value.

Van Hien, when he rejoined his party, urged the importance of getting into McNeil at once, but it was a week later before the expedition went into that neighborhood, and then they did not go near where the gold discoveries were, but staked some swampy ground on the N. E. corner of Argyle township. Finally, disgusted with the way things were being done, Hunt and Van Hien notified the Leader that they were through and asked for an accounting and finally issued writs.

The statements of claim aver that the defendant Laycock "entirely misrepresented his qualifications "and obtained the sums of money hereinbefore men-"tioned from the Plaintiffs upon representations "which were, in fact, untrue. The defendant re-"presented himself as a 'mine-owner' and 'explorer' "'geologist' and 'mining engineer', whereas it be-"came apparent during the operations of the expedi-"tion that the Defendant was not capable of finding "his way in the country to be traversed, was not a "geologist or mining engineer, and had no practical "nowledge of prospecting and spent the time of the "expedition in loitering along well-known water-"ways, and the expedition's time was wasted on ab-"solutely worthless country."

The plaintiffs claim re-payment of the money paid by them to the defendant and for damages, and in the alternative that all accounting he had as between the parties, etc.

Since the issue of the writ the defendant has sold off what household goods he had in Elk Lake and has gone to Toronto.

There is a great deal of sympathy around Elk Lake for the young men who have had their money taken from them in this way. They seem decent chaps, and had they come to Elk Lake, any of the prospectors would have been pleased to give them a start at prospecting without asking any premium.

MAP OF CHU CHUA

The Geological Survey, Ottawa, has published Map 1997, which shows the topography, with 100-foot contour interval, of the Chu Chua creek area on a scale of a mile to the inch. The area mapped is sixteen miles in length, along the North Thompson river, fifty miles north of Kamloops, B. C.

Samson had the right idea about advertising. He took two columns and brought down the house.

If you want to be "free from the body," make it healthy. As Rousseau said, "The weaker the body is the more it commands."

The Recommendations of the United States Coal Commission *

By GEO. OTIS. SMITH
Director, United States Geological Survey

The United States Coal Commission's contract expired September 22 with no legal provision for renewal. But the job is not finished. In the 11 months and 4 days of the Commission's official life an immense mass of information was quickly collected and voluminous reports were hurriedly written. With adequate time available, say at least two full years, its field of investigation might have been more narrowly circumscribed, its lines of inquiry more wisely chosen, the facts it found better selected and arranged, its reports far less voluminous, and its recommendations more definite. It is none too generous praise to term the Commission's reports, made public as yet only in a form primarily for the use of the press, a veritable mine of valuable information, but candor compels the added comment that to prepare the product of this mine for general consumption, some sort of a breaker must be provided — it is not enough to dig up raw, crude facts; they must be sized and separated from associated matter of less value.

Only in part are the recommendations contained in the Coal Commission's twenty-odd reports broadly or analytically stated; hence the reasonableness of a frequent criticism of the Commission and its work. Plainly the Coal Commission needs an interpreter, yet no individual, however close he may have been to the now defunct Commission, can claim any exclusive warrant as authoritative interpreter; the field of constructive criticism, to seek "a wise and efficient policy" for the coal industry, is open to all. Indeed, it is proper to regard the published results of the Commission simply as a starting point. Fortunately, wisdom did not die with the Coal Commission; and we may begin where it left off.

The Commission's Principal Finding

The basic finding of the Commission was its statement of the economic fact that the mining of coal is a business clothed with a public interest, and this but repeats the underlying thought of Congress in providing for fact-finding as a preliminary to legislation. An unfailing supply of domestic and industrial fuel is vital to the general welfare; this means an uninterrupted service in mining and transporting coal, a service that to be efficient and effective must be continuous; and this country-wide dependence upon coal is the compelling reason for some degree of public control of what many citizens prefer to consider a purely private business. If, however, the economic fact that coal mining is an indispensable service can be justly disputed or the legal right of the public to protect the home, nation-wide industry, and interstate commerce can be reasonably denied, it is idle to seek to make a national issue of coal; this Academy and the Congress of the United States might as well devote their thought to the economic and political aspects of asparagus growing, shoemaking, lace manufacture, or any other private business. The Commission finds that coal is vital to America every day and hour.

The first recommendation of the Commission is to let in the light upon the coal business — "the public needs information and the industry needs publicity." Continuous Governmental supervision to find the facts and, in the light of full and up-to-date information, as much governmental regulation as is required to stabilize the industry and protect the public seems to have been the guiding thought of the Commission, with somewhat of a preference, repeatedly expressed but perhaps never sufficiently outspoken, for a minimum of public regulation. Self determination is set up as the ideal for the industry, self determination stimulated by an active and well-informed public opinion.

No Cure-All Available

The year and more in which the coal problem has been given the center of the stage has not sufficed to bring to it the full understanding that is desirable and indeed essential. The continued play of the spotlight has brought out many details but all the fact-finding has not discovered any simple cure-all. This explains the absence of a clean-cut program as the final pronouncement of the Coal Commission; instead, the Commission addresses recommendations of remedial action not only to the Congress but to State legislatures and municipal officials; to the Interstate Commerce Commission and to railroad executives; to coal operators and to mine workers; and finally to the great body of coal consumers, large and small. The finding is one of divided responsibility for things as they are and therefore of distributed obligation to make things different.

The Commission recommended that the Interstate Commerce Commission be made the administrative agency for continuing fact-finding and exercising whatever regulative function is demanded to correct abuses. This recommendation expressed not only a preference for an agency with established policy and prestige rather than a new and untried bureau, but especially the conviction that the intimate relation between transportation regulation and the coal business furnished the logical if not the only basis for the exercise of regulatory powers by the Federal Government.

Over-Development of Bituminous Fields

With adequate supply and reasonable prices as the ends in view, the Commission sought to analyze the workings of the law of supply and demand. The undercapacity of the anthracite mines [illegible] anything but ordinary demand is in marked contrast with the over-development of the bituminous mines, whose capacity far exceeds even the peak demand. In the anthracite industry restraint of trade is unnecessary, for the overdemand maintains price levels; in the bituminous industry no combination or monopoly of producers has ever controlled either supply or prices. With both hard and soft coal, then, the immediate cause of exorbitant prices has been the demand from buyers at times when the supply has been inadequate. The consumer himself can do much, as the Commission recommends, to smooth out the ups and downs of demand, by purchasing coal on annual contract and

* An address presented to the annual meeting of The Academy of Political Science in the City of New York on Tuesday, November 20, 1923.

by providing for storage. To encourage the off-season delivery and storage of bituminous coal, the Coal Commission recommends that the Interstate Commerce Commission allow the commercial ability to sell coal the year round to be the controlling influence in the distribution of railroad cars in months of transportation shortage. Economy in the use of transportation by the encouragement of river movement of coal and by the discouragement of log rail hauls is also recommend. Unfair competition by means of unwarranted freight differentials has favored waste of transportation service, both in making improved waterways ineffective and in promoting the premature opening of mines to serve old markets already well supplied from nearer fields. Thus, mine capacity has outstripped railroad capacity.

Irregularity of seasonal demand and unnatural widening of marketing territory, however, are not the only causes of overdevelopment. The opening of too many mines has been a direct result of the uncertainty of continuous operation due to the uncertainty of labor supply. The periodic and anticipated strikes encouraged a higher peak capacity within the organized territory, and as the strikes increased in severity the coal shortages promoted the opening of more mines in the nonunion fields. Its full monopoly of mine labor in the anthracite region as well as for the larger part of the bituminous tonnage brings the mine workers' union into the foreground of the picture.

The Commission's unequivocal declaration of belief that the union has been potent in bettering the workers' condition but that it can win public approval only as it in turn "accepts in practice the principle that the public interest is superior to that of any monopolistic group, whether employers or employees," might have been condensed into the blunt statement that the union is needed to protect the miner, and the nonunion fields are equally needed to protect the public. But this competition by the nonunion fields, while affording the consumer a large measure of protection as to both price and supply, has cost dearly in other ways, especially in promoting overdevelopment and all the evil consequences that flow from it: too many mines and miners, too short and too uncertain working time, and rates of wages and profits that express to some degree these hazards of employment of both labor and capital. The removal of causes of overdevelopment, therefore, was the subject of several recommendations by the Commission.

These and other recommendations of the Commission relating to taxes, licenses, freight rates, car distribution, inspection of coal, consolidation of mining companies, safety codes, improvement of underground management, larger use of machinery, betterment of living conditions, attention to personnel management, study of the wage structure, and continuous investigation and publicity are all well supported by its findings of fact, * yet each and all of these reforms will fail to stabilize the industry and better the conditions for all concerned if periodic suspensions of mining are to continue. The real issue concerns the sovereignty of the American people in their relation to those who own coal mines or work in coal mines: is the people's right to an uninterrupted supply of coal the dominant right?

Militant Spirit of Miners' Unions

The people's right to a supply of coal at reasonable prices should be equally enforceable against a combination of operators raising the price or a combination of miners shutting down the mines. We have already outlawed combinations of capital attempting restraint of trade or even control of price; a country-wide combination of labor with the declared purpose of enforcing its own decrees by creating public distress would seem even less justified. When its half-million or so members — a sixth of whom do not care to be American citizens — direct their united efforts against the whole people the militant spirit of the mine workers' union takes on the ugly aspect of civil revolt. The open threat of tying up the commerce of a nation and shutting down its industries, the menace of economic chaos, is neither a just nor a legal method of obtaining higher wages for one class of workers in half a dozen States, for surely, the economic rights of the whole body of American workmen are greater than the rights of a small fraction of that body. The mine workers' method of giving a trouncing to their employers is, in fact, giving a clubbing to the public. This dangerous weapon, whether we term it strike or economic force, is one that does violence to the principles of popular government.

The Commission interprets the public attitude as seeking from the unions "satisfactory guarantees of a fair and orderly adjustment of controversies in other ways than by the exercise of economic force" and the practical problem we face is to find a substitute for force. The Commission has recommended voluntary arbitration for settling disputes and has also urged the fundamentally constructive method of building up the day-to-day relations between employee and employer, as well as the method of continuous investigation and timely publicity, yet full success of governmental action of this type, as the Commission realizes, would depend upon the recognition by operators and workers alike of the "finality of the public insistence on continuous operation."

Compulsory Arbitration the Last Resort

If, however, either party to the controversy is unmoved by this "irresistible moral pressure implicit in their joint obligation to furnish the public with coal" it becomes all too obvious that arbitration must be compulsory. The outright rejection by the United Mine Workers at Atlantic City of any arbitration was most disheartening to many who wished the union well. Such use of monopoly power at once forces the issue and the public's right to its coal demands protection from the strike. With that experience so fresh in mind and the threat of a bituminous strike next Spring already heard the Commisssion might well have hesitated to wholly abandon the idea of compulsory arbitration as a legal defence against those who declare industrial war against the whole people. Some of us believed that in default of a voluntary agreement compulsory arbitration would have afforded a more equitable adjustment of the recent anthracite controversy than the terms finally agreed upon. In the bituminous industry, however, compulsory arbitration of a wage scale structure, to be fully successful as an agency of economic welfare, would need to have its awards enforceable throughout all coal fields, whether or

* The best summary of the "Recommendations of the United States Coal Commission," thus far made was presented before the American Academy of Political and Social Science at Philadelphia on November 17 by Edward Eyre Hunt, Secretary of the Commission.

nized or unorganized. If coal mining, like transrtation, is clothed with a public interest so great at its uninterrupted service requires public supersion of settlement of wage disputes, then those wage tes must be governed only by economic conditions, neral and local, not by membership or non-membership in a union. The need of continuity of mine operaon appears to involve mine worker and mine operator ike in a relation to the public quite different from at prevailing in less essential industries, and public fety and general welfare must soon force such legslation as will insure an uninterrupted, supply of al.

The Coal Commission, moreover, sees other possilities for the mine workers' organization: in a tranition from militancy to efficiency, the union thus beming an active agency in improving the individual orker's status; in a program of education in mine fety, where joint action of operator and miner alone an fully protect their common interest; in a drive r Americanization and better citizenship, with the nprovement of local living conditions; and above all, building up the general realization that coal ming at its best is a cooperative enterprise that must be ccessful if it is to yield wages and profits. This mmon interest in continuous and successful operaon is being stimulated in the British coal mines by e present adjustment of wages to results.

Waste by Consumers

Any turn-about-face in the policy and tactics of the nion leaders, however, can not be expected unless a milar reversal is made in the attitude of many of the perators — the employee in his period of dominance as copied all too much the earlier practices of the mployer. Operators, like mine workers, have refused o arbitrate, and arrogance and tyranny were not inented by labor leaders. Yet the Commission has not ubscribed to the belief that business and society are o without hope that what has been wrong in the past an not be rectified either in the present or in the uture.

In addressing advice to the consumer the Commision not only points out his responsibility for exorbiant prices but invites his attention to his own wasteul practices, fuel economy being his means of lowerng heating costs even when coal prices are rising. Throughout the investigation it was evident that veryone in the long line from householder to coal niner wishes someone else reformed and even regulated by law if need be. In fixing the place where something should be done the zeal appears to increase directly as the square of the distance of that place from home, and the average citizen's appraisal of the value of the work of the U. S. Coal Commission is likely to be affected by the direction in which its recommendations are aimed. Recommendations that involve all concerned plainly can not be expected to win general acceptance.

METALLURGICAL TRAINING IN INDIA

The progress of meallurgy in India is well marked by the recent establishment at Jamshedpur, the iron and steel centre in Bengal, of a Metallurgical Institute for the training of young men for the industry. Local governments have joined with the Tata Iron and Steel Co. in contributions for its support. Copper and other ores are mined and smelted in this district in addition to iron.

ADVANTAGE OF AFTERCOOLING COMPRESSED AIR

by F. A. McLean

Under almost all conditions, the atmosphere contains moisture. When this air is compressed and cooled much of the moisture is precipitated, with a resulting shrinkage in volume and the loss of the power consumed in compressing the vapor. This condensation process takes place in ordinary pipe-lines as used around plants, because of the radiation of heat to the atmosphere.

It is a well known fact that moisture in compressed air pipe-lines ultimately reaches the drills or tools. This moisture has two detrimental effects. First, it washes away the lubricating oil, causing excessive wear in the drills with high maintainance charges. The second trouble is that, due to the low temperature caused by expansion of the air in the tool, the moisture freezes in the valves, ports, etc., greatly interfering with the operation of the drill or tool. Production is retarded, if not stopped altogether, by this accumulation of ice.

It has been found from experience that it pays to keep pneumatic equipment working at full capacity as much of the time as possible, even though it may require additional outlay for equipment and power to do so. In most compressed air plants where the air is used for operating rock drills or pneumatic tools, it therefore pays to eliminate the troubles caused by moisture.

Two methods are available; one to take into the compressor dry air only and use it at the tools with as little loss of heat as possible. This is the ideal solution, but it is physically impossible. The second method is to remove as much moisture as possible from the air after it has been compressed, and before it is used in the tools. This can be most readily done by means of an after-cooler, which simply reduces the temperature of the air after compression and precipitates the major part of the moisture.

Due to the reduction in temperature caused by cooling the air, there is also a reduction in volume. This means that a smaller volume has to be transmitted through the pipe line, which in turn means a lesser pressure drop, or a saving in power. This saving in power partially offsets the loss in internal energy caused by the reduction in temperature during the process of cooling.

In addition to the foregoing advantages in the use of an after-cooler, there is another which is worth consideration; there is less expansion of the pipe-lines, due to the uniform and low temperature of the air entering them.

Still another advantage is the precipitation of lubricating oil at a point where it can be easily drained from the system, reducing the rotting of rubber gaskets and hose, if used. The advantages may be summed up as follows:

(1) Elimination of freezing troubles.
(2) Less wear on drills or tools.
(3) More production from men and tools.
(4) Less pressure drop in lines, which means more work for the same power expended in compressing the air.
(5) Elimination of expansion strains in pipe lines.
(6) Removal of oil from air.

THE COPPER SITUATION

The following study of the copper market is from the *Granby News,* published by the Community League at Anyox, B. C., and many be regarded as an informed statement of present conditions.

The wish being father to the thought, the average writer of articles pertaining to industries invariably makes a brave attempt to inject some optimism into his lines, no matter how sad the situation really is. Not so with Mr. G. F. Cheveling, Associate Editor of *The Daily Metal Trade,* whose article in the *Annalist* of recent date tells some cogent truths about the copper outlook. Mr. Cheveling says, in part:

"The curtailment of production in 1921 was undertaken by leading copper producing companies in the U. S. because there was an oversupply of metal due to the inheritance of war time stocks of scrap and virgin copper as well as a high rate of new production. Most of the important mines and smelters shut down in that year. Now in 1923 they are facing a curtailment because the higher cost companies cannot produce for less than 13 cents. Some small properties in Montana have already closed; and all this is happening in the closing months of a year which has seen the largest domestic consumption of copper of any peace time year of copper history. It has been essentially a buyer's market. Had consumption of copper increased in other countries in proportion as it has in the U. S., the present world copper capacity would be short of world demands. Due to political troubles in Europe, this is not so. The post-war consumption of copper for the world has fallen short of pre-war years. In the three pre-war years, export shipments of refined copper averaged over fifty per cent of total American shipments, while in four post-war years the proportion shipped for export dropped to 32.7 per cent, and the proportion shipped for domestic consumption increased to 67.3 per cent. The actual loss and further threatened loss of export copper have played a vital part in the 1923 copper market; and changing from week to week, European politics continue to baffle analysis, and the end is not in sight."

Copper is a true international metal, its trade being unhampered by tariff duties or trade barriers. The entire world copper market seeks a common level the same as water does. The increase or decrease in the demand for copper in any part of the world is reflected in the market as a whole, just as the increase in production in any district of the world has its relative bearing on the market. European consumption of copper is most important to American copper sellers. Fearing that the trouble in the Ruhr would reduce consumption, was a factor in inducing sellers to sell metal to avoid accumulating excess stock. Between March and September 1st, however, stocks of unsold refined copper did not increase. Monthly shipments for the first eight months of 1923 averaged 192,000,000 pounds, while production averaged only 176,000,000 pounds. With September, the situation became entirely different. Total shipments in that month were 160.000.000 pounds, while the production was 200.000.000 pounds. Germany, usually the best customer, bought practically no copper and French takings increased but slightly.

The combined copper output of North and South America is now about 75 per cent of world production. South American copper is now controlled by North American interests. Its development will have a potential bearing upon the market because it is the lowest cost production in the world, the Chili Copper Company having that honor. It will produce 250,000,000 pounds of copper this year. All South American as well as African copper has a direct bearing upon basic American copper price levels, as most of it s brought to the U. S. for refining an immediately assumes a competitive position.

Any analysis of the copper outlook must contain thre considerations. 1. Effects upon world consumption o foreign political conditions. 2. The tendency toward increased supplies of low cost copper produced in oth countries. 3. The outlook for copper business in the lea ing consuming country, the United States. Regardin the first consideration, the European situation continu so uncertain that it is impossible to make any calculati for the immediate future. In spite of all the troub however, Europe has been taking a surprising amount copper. Whether these takings will increase or decrea in the near future, no one can predict. Eventually th takings must increase. Settlement of the reparations question should restore credit and confidence. All th requisites for large European buying exists, except cred and stability, and these await international political co cord, which is so discouragingly slow in making its a pearance. The second consideration, the growth of for eign low cost production, is here to stay. In times of d pression, this low cost copper production is bound to su plant higher cost U. S. copper. In respect to the third consideration, the outlook is dependant upon general business in the United States. In 1923, the electric ind took 60 per cent of all copper used in the country, wh not a little was taken by the building trades and automo bile industry.

Copper is undeniably cheap at the present time. Its average for the past twenty years has been slightly ov 17 cents. Without doubt copper will again sell for mor than thirteen cents. In the meantime, there is no com modity in the production of which the struggle for th survival of the fittest is more pronounced than in the case of copper. The large interests are just as much concerned as the smaller producers. Mr. Cheveling does not see any possibility of a general shut down such as occurred in 1921, but expects that the next reduction in output will be brought about by the enforced closing of the higher cost companies. Just how much lower the price will have to drop to bring this about cannot be fore cast; for up to a certain point it is less costly to operate at a loss than it is to close down completely.

ELECTRICAL CONDUCTIVITY OF REFRACTORY MATERIALS AT HIGH TEMPERATURES

Reliable and comparable data are needed on the electrical resistivity at high temperatures of the refractory materials suitable for furnace linings. In the performance of experimental work by the Bureau of Mines Ceramic Experiment Station, Columbus, Ohio, methods and apparatus for making such measurements have been developed. Test pieces for determination of the electrical resistance were prepared from fire clay, kaolin, alundum, diaspore, thoria, silica, crystal magnesite, silicon carbide, sillimanite, zirkite, and magnesium spinel. Resistance measurements have been run on half the pieces. Carbon electrodes are employed, measurements being run in an atmosphere of pure nitrogen to a temperature of 1400 deg. C. in a gas-tight platinum-resistance furnace.

THE MINING DISTRICTS

BY THE JOURNAL'S CORRESPONDENTS

NORTHERN ONTARIO

Hollinger's Progress. — With the last dividend cheque, the Hollinger sent out an interim report to its shareholders, covering the year to October 7th. A good deal of the information regarding the operations of the company has been given in recent issues of the "Canadian Mining Journal". A large part of the report is devoted to the question of power and litigation. The company states that the power development at Island Portage on the Abitibi River is being pressed with all possible dispatch, with a view to its completion by the first of August, 1924.. Contracts for practically everything has been let, except for the clearing of the right-of-way. A spur line connecting the power site with the T. & N. O. Ry. will soon be completed, a total of 450 men being employed on the work. The report states that the immediate development contemplates two units of 12,500 h.p. each, with provisions to increase to the full capacity of the Abitibi river at this point when the demand for power warrants it, and that notwithstanding reports to the contrary, the permission of the Ontario Government was obtained for the development of the power based on a 60-foot regulated head. The question of power disputes now before the courts is also dealt with at some length.

Porcupine. — It is reported that the Premier Paymaster and United Mineral Lands properties in Porcupine will be amalgamated. These two properties, which adjoin, are controlled by Boston people, headed by E. H. Walker, which also owns properties in Butte, Montana, of which the principal one is the Crystal Copper Company. Some spectacular gold has been found on both the Paymaster and the United Mineral Lands, and on the former property a shaft has been sunk to a depth of 600 feet, and will be continued to 1,000 feet. On the United Mineral Lands a good deal of diamond-drilling has been done, which is stated to have proven the existence of high-grade ore-bodies to a depth of 1,000 feet. A number of workmen's houses are being built, which will enable the company to largely increase its working force, and equipment is being installed for the complete electrifying of both properties. When this installation is completed, a shaft will be sunk on the United Mineral Lands, and as the shaft on the Paymaster is deepened, levels will be opened at 600, 800 and 1,000 feet. It is stated that half a million dollars has been spent on these properties to date, and that the plans of the company call for the expenditure of approximately one and one-half million dollars, which will include the building of a mill.

It is understood that at present Dome costs are below $4.00 a ton, and as the ore is averaging about $12.00, this leaves a very substantial margin of profit. The company has a sufficient supply of both labor and power, and although no announcements have been made recently regarding developments, they are understood to be satisfactory.

At the annual meeting of the Goldale, it was stated that negotiations are on foot for the amalgamation of the Goldale, Plenaurum and Armstrong Booth, but nothing has yet been concluded, and it is understood, from outside sources, that negotiations are practically at a standstill. The reason for this is that in the Plenaurum company, which is a necessary part of the proposed merger, the McIntyre holds over 40 per cent. stock interest, and that company prefers to take acreage for its stock rather than go into a new company. This is not satisfactory to the other interest involved, and neither party appears to be able to get control. It was stated at the meeting that if the development on the 1,000-foot level succeeded in finding sufficiently large bodies of commercial ore, the Schumacher mill might be either purchased or leased, and that to bring the property to a producing stage and build the necessary tramway and make the necessary alterations to the mill, would require an outlay of approximately $100,000.

Kirkland. — The annual report of the Teck-Hughes for the year ending August 31st shows a record income of $998,000, of which $530,000 was profit. The company now has sufficient funds to pay off the bonds, which mature next January, and to provide a surplus of approximately $300,000. During the year the mill treated 34,690 tons, and recovered bullion to the value of $981,500, or an average of $28.30 a ton, which is a record for Ontario gold mines. Gross recovery was $981,000, operating costs being $400,000, or $11.55 a ton. Broken ore reserves now stand at 36,256 tons, and total ore reserves are shown at 126,683 tons, averaging $20.00 a ton, which is an increase in gross value of $1,350,000, as compared with the previous year. Development was continued to a depth of 1,100 feet, and the work done during the year continued to be satisfactory, particularly on the Orr property, which the company purchased. It is understood that during the month of October production amounted to $93,000.

Better results are being obtained at the Argonaut Mine, and not only is the tonnage being increased, but the grade of the ore is better. The mill is now treating approximately 100 tons a day, of about $15.00 grade, which allows a substantial margin of profit. During 18 days in October, which was a short month on account of the break-down of some of the mill machinery, the mill averaged 102 tons a day and recovered $23,500.

A recent discovery has been made at a depth of 180 feet on the Lebel-Oro, which appears to be of importance, as assays running from $6.00 to over $250.00 for a width of about 6 feet have been obtained.

At a meeting of the Bidgood, which is to be held shortly, shareholders will be asked to ratify a proposal of the directors to sell its assets to a new company, which it is proposed to form. The new company is to be capitalized at $3,000,000, and one share of the new company will be given for each two shares in the old company, which will leave 1,500,000 shares in the treasury. This treasury stock is for the purpose of providing further money for the development of the property. It is stated that several offers have been made, and it is understood that the McKinley Darragh is interested.

BRITISH COLUMBIA

Institute Meeting at Nanaimo. — At the annual meeting of the Canadian Institute of Mining and Metallurgy (Vancouver Island Division) held at Nanaimo on October 31st last, officers were elected as follows: Chairman, Charles Graham; General Superintendent Canadian Collieries (D) Ltd.; Vice-Chairman, C. M. Campbell, General Superintendent Granby Coal & Coke Co.; Secretary-Treasurer, Wm. H. Moore, Western Fuel Co., of Canada; Executive, George O'Brien, Cumberland; Robt. Henderson, Nanaimo; Charles Touhey, Cassidy; and T. A. Spruston, Ladysmith. An address was given by Hugh F. Marriott, of London, England, who was passing through the province in the course of a tour of the Empire. He explained that he was working on the organization of an Empire Federation of Mining Engineers, that he had visited South Africa, Australia, and New Zealand with good results, and that he was desirous of obtaining the co-operation of all in making the Empire Exhibition of next year in London an outstanding event in point of its mineral exhibits, as well as by developing a closer union and a better understanding among men of the profession throughout the Empire.

Trail Ore Receipts. — Ore receipts at the Trail Smelter, Consolidated Mining & Smelting Co., for the week October 22nd to 31st, totalled 7,383 tons. The detailed shipments follow:

	Tons
Alamo, Alamo	102
Bell, Beaverdell	43
Company Mines	5,989
Cork Province, Zwicky	148
Elkhorn, Sandon	4
Gem, Sandon	25
Knob Hill, Republic Wn.	136
Lightning Peak, Edgewood	2
Lone Pine, Republic Wn.	310
Paradise, Invermere	69
Quilp, Republic Wn.	166
Sally, Beaverdell	47
Sailor Boy, Crawford Bay	8

Flood at Anyox. — Some fifteen inches of rain fell at Anyox, headquarters of the Granby Consolidated Mining & Smelting Co., in little more than three days and resulted in a mudslide that damaged the dam and otherwise interfered with the Company's operations. The plant was idle for the week commencing the 4th November, repairs necessary to permit resumption not having been completed until Saturday the 10th November. This is an unusual occurrence although the northwest coast of British Columbia has a reputation for heavy rains.

Indian Mines Stock. — There is considerable local interest in the announcement that the Indian Mines Ltd., operating in the Portland Canal district of British Columbia, has been listed on the Montreal stock exchange. This is the first company with holdings in the Salmon River section of the new western Canadian mining camp to go on the Canadian stock exchange boards.

Interest in Whitewater District. — Reports of the mineral riches of the Whitewater district, an area of exceptional promise northeast of Lillooet, have been in circulation recently. The region is set among mountain ranges and so is difficult of access. It is practically virgin ground, the high rock walls with which it is girded having discouraged prospecting in the past and having dampened the enthusiasm of settlers who might have been attracted by the wonderful fertility of its soil.

A few years ago the Provincial Department of Mines, presented with apparently reliable information regarding extensive deposits of limonite ore in the Whitewater, appointed an engineer to spend a summer in the district investigating the commercial possibilities of these deposits. The report was that considerable bodies of the ore existed but that the tonnage was not as great as had been represented; that while limonite covered large areas, boring showed there was little average depth to the material. As an important source of ore it was thus relatively unimportant, especially in view of the fact that actual mining operations would have to be preceded by the provision, at much expense, of adequate transportation facilities.

Resident Mining Engineer's Statement. — While however, the report on the bodies of limonite was unsatisfactory economically, the activity of the Department of Mines threw the light of publicity upon the Whitewater district and stimulated general prospecting. The discovery of tellurides of gold was announced and the arrival of a miner carrying a substantial amount of gold, taken from his property by the most primitive means, caused a stir in mining circles of the Coast. Since then the district has been more thoroughly prospected and many claims have been staked, some being partially developed. Owing to the tendency to exaggeration found in frequent newspaper references to the size of high-grade ore bodies uncovered in the Whitewater district, Major A. W. Davis, resident government mining engineer, who visited the section this year, has issued the following brief but frank statement:

Editor Province — There is so much publicity being given the Whitewater district, west of Lillooet, that I consider it necessary to make a few remarks on the matter myself. I take it that the general public is entitled to my idea of the situation in view of what I consider the misleading descriptions of the area which are being spread around the country.

To be brief I consider the Whitewater a likely place for prospecting, although at the time of my last visit in August, this year, nothing had been opened up that would reasonably ensure a producing mine on a permanent basis. The Windfall group at that time had a lot of rich float in evidence, but very little ore in place and several hundred feet of underground work then in existence had failed to produce any. I, however, consider it quite a legitimate gamble to continue looking for it. In this connection I wish to call attention to the fact that the high assays I got in 1922 on this property, which are quoted in the prospectus of the company operating the group, do not represent any tonnage.

The Massena group, operated by the company controlling the Windfall Mine, I visited in 1922 and also this year. I find that there is no justification in fact for the extravagant claims made for the property by this same company as late as this summer. There is

no tonnage of ore of a commercial grade in evidence on the ground.

Accounts of the district describing it as a second "Rand" and in which enormous dykes showing coarse gold are referred to are not true. The genuine prospector does not benefit by this kind of thing. Not much money changes hands nowadays before the purchaser has looked over the ground and this kind of thing creates the wrong atmosphere for the visiting investor and possibly turns him against some claim which with development might turn out successfully.

A. W. DAVIS,
Resident Engineer.

Kamloops, November 10.

ALBERTA

There was a conference recently between Hon. Charles Stewart, Minister of the interior in the Dominion Government, and members of the Government of the province of Alberta with a view to having the province take over the supervision of fuel conservation work in conjunction with the regular inspection of mines. The latter now is the duty of the Province. Hon. Mr. Stewart explained that it was hoped that the present overlapping between the two governments would be eliminated. He pointed out that the Dominion now is mainly concerned in the question of the conservation of fuel and it was felt that the Province might undertake this work as well as the regular inspection of mining operations.

NOVA SCOTIA

Increased Coal Output. — The coal outputs of the Dominion collieries are still increasing. The latest high day bordered on 18,000 tons, and yet, early in the year, we counted 15,000 tons a large day's work. Surely with two collieries still idle such outputs should be very satisfactory even to a corporation reaching for big things. It goes to show that Nova Scotia has both the mineral and the men who can mine it, and there is little need to go outside the province for expert mining men. This is fully realised by the public at large and although now and again a little advice from those of other districts may be helpful, the burden and responsibility of the mining falls to the lot of the native sons of the province.

Steel Plant Council in Action. — The Sydney Steel Plant Council have taken up the matter of the eight-hour day and are making a preliminary survey. At first sight it appears a simple question, but closer acquaintance proves its complexity. It has many sides and some of these are rather thorny. This has been the experience of one of the largest steel corporations of the United States. An eight-hour day and six days a week seems ideal for the steel industry. But all the workmen wanted to have Sunday off, and all objected to the reduction of pay consequent upon the shorter hours. Nevertheless many realize that the short day and the weekly rest day have come to the steel industry to stay, and here in Nova Scotia, as in the United States, all will settle down into the new habits. It is very satisfactory to have the matter in the hands of the Sydney Steel Plant Council for adoption and adjustment.

Demonstrations with Explosives. — Since the visit of Edward Godfrey of the Canadian Explosives Limited there has been much activity among the shotfirers of Cape Breton collieries. Taking advantage of his visit, the Dominion Coal Company, believing there is always something new to learn, had Mr. Godfrey conduct a few experiments with the explosive in most general use — Monobel No. 3. Thinking it might be useful to be able to tell when the explosive is at full strength, Mr. Godfrey demonstrated the matter in a very simple way. Taking a cartridge of Monobel, he cut it in halves and wrapped it up in paper, taking care to keep an air space of six inches between the two parts. On setting off the detonator the air space was bridged and the explosive was set off. Defective powder will not give results over this distance and sometimes an air space of two inches will not be bridged. To show that there is a right and wrong way of inserting the detonator, it was put into the cartridge on an angle instead of directly in the end. It failed to jump the six inch space and got down as low as one inch. There is even a difference in the end in which the detonator is put into the cartridge, if the explosive has absorbed moisture. It was pointed out by Mr. Godfrey that the open end of the cartridge is the first to be affected by moisture and to be sure that perfect detonation takes place the detonator should be placed in the opposite end.

Since this demonstration the Chief Inspector of Mines, Alexander McEachern, has had all the shotfirers at the collieries fully instructed in the proper method of placing detonators in cartridges. This may appear a very simple matter, but those who mine coal know the dangers and delays of mis-shots, and a little knowledge gained in this way may save time and keep the miner from running unnecessary risks.

The visit of Mr. Godfrey was an education to the busy mine officials of Cape Breton and a means of education to the men who use explosives in the mine each day. It will help to make mining safer for explosives cannot be handled too carefully. Again there is much saving to the miner, who has to pay for the explosives, in knowing how to obtain the best results.

CHARCOAL PRECIPITATION FROM CYANIDE SOLUTIONS

Research work is being continued by the Department of the Interior at the Rare and Precious Metals Experiment station of the Bureau of Mines, Reno, Nevada, to determine whether the use of charcoal for precipitating gold and silver from cyanide solutions is feasible. If charcoal could be used, it would have many advantages on account of its cheapness. It has been found that charcoal would precipitate gold and silver from a cyanide pulp (ore and cyanide solution) and that this loaded charcoal could be readily floated away from the pulp. Counter current charcoal precipitation on Tonopah Extension mill solution proved satisfactory, acting very quickly with complete precipitation on fresh [illegible]. Many kinds of charcoals were tested, and many different treatments of charcoal tried for their precipitating efficiencies. For general conditions it seems that no charcoal has any outstanding advantage over any other. Most treatments of charcoal that give advantageous results can be traced to a heat treatment whereby oxidation of the inert carbon is effected either by air or steam. Very few fouling agents in cyanide solutions affect the precipitation of gold and silver on charcoal. One of the principal problems is to recover the precipitated metals.

A number of solvents were found for the gold or silver precipitated on charcoal. These generally act much more vigorously if hot. A hot cyanide solution is a very effective solvent for both gold and silver. Hot water dissolves a considerable amount of the gold and silver.

Electrolytic separation of the precipitated gold or silver on charcoal from cyanide gave only indifferent results and does not appear promising.

Promising results were obtained in the use of sodium sulphide in connection with charcoal as a silver precipitant. Cyanide is regenerated in this case, and excess of sodium sulphite is taken care of by absorption on the charcoal if the excess is not too large. This sulphide charcoal precipitation is detrimental, however, in gold precipitation.

The theory that some chemical treatment of a loaded charcoal would so change the absorbed gold and silver as to re-activate the charcoal for a new load was given some attention. Such a chemical may be called a "fixer". It was found that nitric acid has some power as a fixer, but that hydrochloric acid has none. More experimental work is needed to determine whether reactivation would be a feasible step in a charcoal process. Much progress has been made by the Bureau of Mines in working out the chemistry of the process, and fundamental data have been obtained on the mechanism of the precipitation of gold and silver on charcoal.

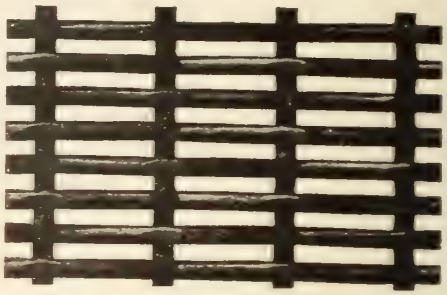
CONVERSION OF CLAYS TO ALUMINUM SULPHATE

In connection with the development of a simple cheap process of preparing pure solutions of aluminum sulphate, work has been undertaken by the Department of the Interior at the Pacific Experiment Station of the Bureau of Mines on sulphating clays by various methods. Sulphate roasting, using gases containing varying amounts of sulphur dioxide to sulphate the aluminum silicate of the clays proved impracticable, but favorable results were obtained by treating the clays with sulphuric acid. A wide series of aluminum silicate products was treated at various temperatures with differing strengths of acid. In general, nearly all the silicates were decomposed with fair efficiency at temperatures up to 200° C. and with acids containing 50 per cent to 70 per cent sulphuric acid. The easiest silicate to decompose was bentonite, but many of the kaolins were quite easily attacked. Feldspars are much more resistant. These experiments are being conducted by G. S. Tilley, assistant physical chemist.

MOVEMENT AGAINST U. S. ARSENIC DUTIES

A movement has been organized in the southern United States with a view to securing the importation of arsenic free of duty. Only ten per cent. of the cotton crop was treated with arsenic compounds during the past season, and the ravages of the boll weevil continue almost without abatement.

POSITION WANTED—Position as assistant in metallurgical laboratory by graduate in chemistry of Technical School. Box 626, Canadian Mining Journal, Gardenvale, Que.



GREENING'S

Ton Cap Screens

The service of any Greening product can never be measured by its first cost. The use of the finest materials, precise standards of manufacture and careful workmanship reflect themselves in increased satisfaction for the user, longer life and a reduction in final cost.

Greening's Ton Cap Screens increase profits by increasing tonnage. This screen will not bend nor clog and its unusual durability means economy.

HAMILTON, ONT.
MONTREAL, QUE. WINNIPEG, MAN.
Makers of Wire Rope, Wire Screens, Perforated Metals for sixty years.

Sheriff's Sale

Of Valuable Mining Property
County of Lennox and Addington

TO WIT:

By virtue of a Writ of Fieri facias issued out of the Supreme Court of Ontario to me directed and delivered against the goods and chattels, lands and tenements of J. A. Seybold, defendant arising out of the suit of L. P. Hughes, administrator of the estate of A. M. Chisholm, vs J. A. Seybold, I will offer for sale by tender en bloc or separately all the mining interests in the North Half of Lot Number Five (5) in the Fourteenth Concession of the Township of Sheffield containing one hundred acres more or less known as Chisholm's Mine and also a quantity of heavy mining machinery consisting of rolls and flotation table.

On the property is a blacksmith shop, large building for processing and other buildings.

The ore is said to be molybdenite ore and other valuable minerals.

Tenders will be opened at my office at the Court House in the Town of Napanee on Thursday December 28th, 1923 at 2 o'clock P. M. Each tender must be accompanied by a certified cheque for ten percent of the sum tendered which will be returned to the tenderer in case his offer is not accepted. The highest or any tender not necessarily accepted. Envelopes to be marked "Tenders for Mine."

MINES BRANCH

Recent Publications

Talc and Soapstone in Canada, by H. S. Spence.

Titanium, by A. H. A. Robinson.

Summary Report of Investigations made by the Mines Branch during the calendar year ending Dec. 31, 1921.

Phosphate in Canada, by H. S. Spence.

The Preparation, Transportation and Combustion of Powdered Coal, by John Blizard.

Road Materials along the St. Lawrence River, from Quebec Boundary to Cardinal, Ont., by R. H. Picher.

Barium and Strontium in Canada, by H. S. Spence.

The Coal-fields and Coal Industry of Eastern Canada, by F. W. Gray.

Analyses of Canadian Fuels. Part I to V, by E. Stansfield, M. Sc., and J. H. H. Nicholls, M. Sc.

Graphite, by H. S. Spence.

Gas Producer Trials with Alberta Coals, by J. Blizard and E. S. Malloch.

The Mines Branch maintains the following laboratories in which investigations are made with a view to assisting in the developing of the general mining industry of Canada:—

Fuel Testing Laboratory.—Testing value of Canadian fuels for steam raising and production of power gas; analyses, and other chemical and physical examinations of solid, liquid and gaseous fuels are also made.

Ore-Dressing Laboratory.—Testing of Canadian ores and minerals, to ascertain most economical methods of treatment.

Chemical Laboratory — Analyzing and assaying of all mineral substances and their manufactured products. Copies of schedules of fees, which are slightly in excess of those charged by private practitioners, may be had on application.

Ceramic Laboratory.—Equipment is such that complete physical tests on clays and shales of the Dominion can be made, to determine their value from an economic standpoint.

Structural Materials Laboratory.—Experimental work on sands, cements and limes is also undertaken.

Applications for reports and particulars relative to having investigations made in the several laboratories should be addressed to **The Director, Mines Branch, Department of Mines, Ottawa.**

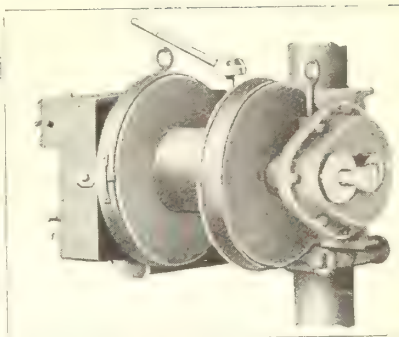
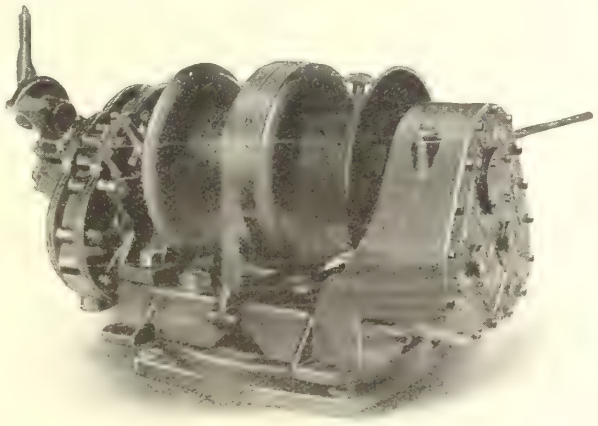
"The Waugh Way Wins"

Model 3 Leadville Column Hoist.

Model 5 Super-Leadville Column Hoist.





Cable Side, Model 300 Turbro Waughoist

Single or Double Harness?

COLUMN-HOIST work requires only a single-harness machine of either 3 or 5-HP. while slushing or scraper-mining necessitates a double-harness machine of sometimes 10-HP.

WHETHER your problem involves either single or double-harness, it can be solved to your complete satisfaction by one of these three well known hoists: Model 3—3-HP. Leadville; Model 5—5½-HP. Super-Leadville; or Model 300—10-HP. double-drum Turbro Waughoist.

LEADVILLES, (manufactured by THE William A. Box Iron Works Company, of Denver, Colorado), are now sold exclusively by this company in connection with its Turbro Waughoists. Write today to the nearest Waugh branch office for descriptive booklets.

Sheriff's Sale

Of Valuable Mining Property
County of Lennox and Addington

TO WIT:

By virtue of a Writ of Fieri facias issued out of the Supreme Court of Ontario to me directed and delivered against the goods and chattels, lands and tenements of J. A. Seybold, defendant arising out of the suit of L. P. Hughes, administrator of the estate of A. M. Chisholm, vs J. A. Seybold, I will offer for sale by tender en bloc or separately all the mining interests in the North Half of Lot Number Five (5) in the Fourteenth Concession of the Township of Sheffield containing one hundred acres more or less known as Chisholm's Mine and also a quantity of heavy mining machinery consisting of rolls and flotation table.

On the property is a blacksmith shop, large building for processing and other buildings.

The ore is said to be molybdenite ore and other valuable minerals.

Tenders will be opened at my office at the Court House in the Town of Napanee on Thursday December 28th, 1923 at 2 o'clock P. M. Each tender must be accompanied by a certified cheque for ten percent of the sum tendered which will be returned to the tenderer in case his offer is not accepted. The highest or any tender not necessarily accepted. Envelopes to be marked 'Tenders for Mine.'

For The Small Mine or Quarry

"Ingersoll-Rand" Compressors and Drills

THE small compressor for furnishing air to three or four rock drills, a small hoist or pump, should be as efficient, reliable and as nearly automatic in tion as modern design and skilled workmanship can ake it.

Efficient because the lower the cost of compressing r, the greater the saving at the time when funds are ost badly needed and hardest to get.

Reliable because the property is often miles from a ilroad; there is usually only one compressor and if it reaks down work will be held up until repairs can be mpleted.

Automatic because the services of a skilled engineer re seldom available and the operator's time can often be sed to better advantage in other ways.

For the small mine or quarry there is no simpler or better combination than an "Ingersoll-Rand" Class ER or FR Compressor and Ingersoll-Rand "Jackhamers" or Convertible Drifters and Sinkers.

Furthermore, you can always satisfy yourself before buying as it is easy to locate nearby installations where the worth of this combination is being constantly proven.

Class ER and FR Compressors are straight-line, single-stage, double-acting units fitted with Ingersoll-Rand Plate Valves. They are simple, sturdy, compact in construction, reliable, automatic and economical in operation. Class E R units are furnished for long or short belt drive; Class FR for steam drive.

Write our nearest branch for bulletins and names of users in your locality or outline conditions and we will recommend a complete plant to meet them.

Ontario's Minerals

PROVINCE OF ONTARIO

Hon. CHARLES. McCREA, Minister. DEPARTMENT OF MINES *Thos. W. Gibson*

Mineral Areas

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favourable for the occurrence of minerals 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver veins of Cobalt, Gowganda and South Lorrain occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

Economic Minerals

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario: — actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluorspar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, Portland cement, brick and tile, meet every demand.

Mineral Production

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1922 to be worth $62,202,169, of which the metallic production was $38,190,711.

The following figures show the growth of Ontario's mineral industry by five-year periods since 1891 when a Bureau of Mines was first established.

Year.	Value.	Year.	Value.
1891	$4,705,672	1911	$41,976,797
1896	5,235,003	1916	65,303,822
1901	11,831,086	1918 (Maximum war output)	80,308,972
1906	22,388,383	1921	48,128,387
	Dividends.		

Dividends and bonuses paid to the end of 1922 amounted to $28,096,699 for gold mining companies, and $86,238,185 for silver mining companies or a total of $114,334,884.

Mining Regulations

A miner's license costs $5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of $2.50 or $3.00 per acre, depending on location in unsurveyed or surveyed territory.

Assay Office

The Provincial Assays Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

Publications

Thos. W. Gibson,
Deputy Minister of Mines.
TORONTO, CANADA

BRITISH COLUMBIA

The Mineral Province of Western Canada

Has produced Minerals valued as follows: Placer Gold, $76,542,203; Lode Gold, $109,647,661; Silver, $59,814,266; Lead, $51,810,891; Copper, $170,723,242; Zinc, $24,625,853; Coal and Coke, $238,289,565; Building Stone, Brick Cement, etc., $36,605,942; Miscellaneous Minerals, $1,358,839; Making its mineral production to the end of 1922 show an

Aggregate Value of $769,418,462

The substantial progress of the Mining Industry of this Province is strikingly exhibited in the following figures, which show the value of production for successive five-year periods: For all years to 1895, inclusive $94,547,241; for five years, 1896-1900, $57,607,967; for five years, 1901-1905, $96,509,968; for five years, 1906-1910, $125,534,474; for five years, 1911-1915, $142,072,603; for 5 years, 1915-1920, $189,922,725; 1921, $28,066,641; for the year 1922, $35,158,843.

Production During last ten years, $339,280,940

Lode-mining has only been in progress for about twenty-five years, and not 20 per cent. of the Province has been even prospected; 300,000 square miles of unexplored mineral bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than those of any other Provi[illegible] in the Dominion, or any Colony in the British Empire.

Mineral locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full information, together with Mining Reports and Maps, may be obtained gratis by addressing.

VICTORIA, British Columbia

THE HON. THE MINISTER OF MINES

PROVINCE OF QUEBEC

MINES BRANCH

Department of Colonization, Mines and Fisheries

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, etc.

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

MINER'S CERTIFICATES. First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. The price of this certificate is $10 and is valid until the first of January following. This certificate gives the right to prospect on public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres.

WORKING CONDITIONS. During the first six months following the staking of the claim, work on it must be performed to the extent of at least twenty-five days of eight hours.

SIX MONTHS AFTER STAKING. At the expiration of six months from the date of the staking, the prospector, to retain his rights, must take out a mining license.

MINING LICENSE. The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cents an acre per year, and a fee of $10.00 on issue. It is valid for one year and is renewable on the same terms, on producing an affidavit that during the year work has been performed to the extent of at least twenty-five days' labour on each forty acres.

MINING CONCESSION. Notwithstanding the above, a mining concession may be acquired at any time at the rate of $5 an acre for SUPERIOR METALS, and $3 an acre for INFERIOR MINERALS.

The attention of prospectors is especially called to the territory in the Northwestern part of the Province of Quebec north of the height of land, where important mineralized belts are known to exist.

PROVINCIAL LABORATORY. Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY, 228 ST. DENIS STREET, Montreal, for the determination, assays and analyses of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equipped laboratories of this Institution and its trained chemists ensure results of undoubted integrity and reliability.

The bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of the Province, on application addressed to

HONORABLE J. E. PERRAULT,

MINISTER OF COLONIZATION, MINES AND FISHERIES, QUEBEC

Decrease your grinding costs.

USE HISCO BALLS

"If quality counts use 'Hisco' Products" *Hisco Balls* are noted for superior quality. They are in use in the largest ore and cement mills from Halifax to Vancouver. Forged from Electric Furnace chrome steel, absolutely the best ball on the market.

Sizes 3, 4, 5 and 6 inch carried in stock.
Special sizes from 6 inch up made to order.

Serving Canada's Mining Industry

It is many years since The Imperial Bank of Canada, recognizing the importance of the Canadian Mining Industry and realizing the need of banking facilities for those engaged in its development, first opened a branch in Northern Ontario.

Since then the Imperial Bank's service has gradually extended until the mining interests in the rich area between North Bay and Hearst are now linked up by a complete chain of 12 branches.

This Bank's service to the mining industry is not confined to Northern Ontario alone. In all the mining areas throughout Canada the "Imperial" is rendering a valuable and complete financial service.

IMPERIAL BANK OF CANADA

Peleg Howland, President. A. E. Phipps, General Manager

The Kromhout Gives Dependable Service Under The Most Exacting Conditions:

The following letter received from a famous Hudson's Bay Captain in reference to a 20 year old KROMHOUT engine, testifies to the fact that the KROMHOUT will stand abuse as well as use.

The steel motor vessel "NEOPHITE" was built in 1903, and installed with a 50 B.H.P. KROMHOUT Oil Engine. For ten years she was used in European waters, maintaining a freight service between Holland and England. In 1913 she came to Canada, crossing the Atlantic under her own power. She was sent to the Hudson's Bay by the Railways and Canals Department in 1913, and was used for lightering from the large ships at the Port Nelson terminals until 1917 being in continuous service.

During the period of her service in Hudson's Bay, the "NEOPHITE" was commanded by me and gave excellent service, the engine in particular being reliable and efficient, and giving no trouble; we never lost a tide, and the engine to my knowledge never refused duty.

I have no hesitation in recommending this type of engine to anyone requiring economical power for commercial vessels.

Yours faithfully,
MASTER.

We have a book full of similar testimonials from all parts of the world. Send for it if interested.

THE CRUDE OIL ENGINE COMPANY OF CANADA.

14 Place Royale, MONTREAL.

:-: EDITORIAL :-:

GOLD EMBARGO SUSPENDED

In the *Journal* of the 16th. inst. reference was made to the proposal of Hon. Mr. Fielding, Minister of Finance, to pay for Canadian gold in Canadian funds, while maintaining the embargo upon its export. This proposal never actually came into effect, and the story is an interesting one.

The objections to the course proposed were placed before the Minister of Finance by representatives of the gold-producing companies, but from the published accounts, it would appear these gentlemen received little comfort, the Minister remarking that the companies could better afford to lose the difference in exchange than could the Government. Never before in a British Dominion has so extraordinary an attempt at confiscation been made. To compel Canadian companies to sell their gold to the Canadian Government and take their pay in Canadian currency, depressed below par, while in the United States there was a ready market at $20.67 per ounce in American currency, was simply to rob the companies of the difference, for the Government could immediately ship to New York the gold they purchased and be paid for it in U. S. dollars. On last year's output the profit on the transaction would be over $400,000.

It is obvious that the Government proposal if put into effect, would strike a blow at the gold basis of our currency. In principle it would be equivalent to the German Government compelling gold mining companies in that country, if there were any, to hand over their product in return for German marks, the value of which at present is, say, one billion for a postage stamp. The great mines of the Rand in South Africa are permitted to sell their gold in London at the market rate, which depends upon the rise or fall of the pound Sterling. In 1920, the price of gold in London rose to 120 shillings per ounce, and the President of the Transvaal Chamber of Mines stated that, with working costs as they then stood, 16 mines at work would be making a loss when gold dropped to 100 shillings an ounce; when it dropped to 90 shillings per ounce, the number of mines affected would be increased to 26, and when gold returned to its normal price of 85 shillings, 31 mines would no longer pay for the working. The price of gold in London at the present time is about 92 shillings, but the predicted effects in the Transvaal have been to a large degree averted by reason of a reduction in working costs. Nevertheless, the margin in some mines is small. But neither the Government of the South African Union nor the British Government, notwithstanding the bitter taxation in England, ever attempted to lay hands on the margin between the price as measured by the depressed pound, and the price when sterling is at par. We hope Canadian currency will soon return to the par level; but if it should sink still further, the effect of any such move as Mr. Fielding proposed would be correspondingly injurious. In principle the suggestion was wrong; it would frighten capital, instil a lack of confidence in Canadian laws, and hold up the Canadian ideas of justice before the world as modelled on those of the Soviet Government of Russia.

On the return of the gold companies' representatives from Ottawa, Honourable Chas. McCrea, Minister of Mines for Ontario, telegraphed Mr. Fielding protesting strongly, and asking for an appointment. Mr. Fielding fixed Wednesday morning, 14th. November; and, accompanied by a large delegation, representing British, American and Canadian investors and producers, Mr. McCrea went to Ottawa, and all the above objections and others were plainly laid before Mr. Fielding. To his credit, be it said, Mr. Fielding saw the light, and the same day gave a statement to the press to the effect that the Government desired to take further time to consider the question of lifting the embargo, but that meanwhile "in cases arising, licenses to export bullion would be granted to the companies".

It is evident Honourable Howard Ferguson has a "live wire" in his Minister of Mines.

FORT NORMAN OIL FIELD

Last year Dr. George S. Hume, of the Geological Survey, contributed to these pages on his return from the field a summary account of his investigations in the Fort Norman oil area. Today we are pleased to present a resumé of what he has learned during the season just closed, and some of his conclusions. It will be noted that Dr. Hume suggests that the work of the Imperial Oil Company in that area has been suspended, not abandoned. His recommendations for more drilling serve to indicate that further investigation will be fruitful of at least important geological data.

It is a privilege to be able to present to our readers authoritative information such as this, almost or quite a year in advance of the official report. We feel that

the policy that not only allows but encourages the technical officers of the Department of Mines to present these advance reports for public use through the public press is worthy of the highest commendation.

BLANKETED GROUND IN THE GOLD BELT

The past season's activities in the western part of the Quebec gold belt has showed up a serious fault in the laws that govern staking and assessment work. At least eighty per cent. of the land held under prospectors' licenses or permits has been merely blanketed; that is, it has been held without the performance of any real prospecting work. On some of this land assessment work has been sworn to that was never performed; but the majority of the claims thus witheld from active development of any kind have been held by other means.

Under the present regulations, a claim can be held for six months without obligation other than buying a license, staking and recording. At the end of that time assessment work and a tax of fifty cents an acre are due. There is more than one way of circumventing these regulations. The past season's experience has shown that a common way is to "trade" claims. A few days before the assessment work and cash payment on two claims in separate localities are due to be recorded, the separate owners will post up notices of abandonment and each will re-stake the other's claim and record it — free from duties for another six months plus the allowance for winter weather. By this means much land witheld from active development during the season just closed will remain again during the summer of 1924 in the hands of speculators who have no intention of spending time, effort or money on their claims.

In spite of the unusually encouraging results of exploration in Rouyn and Boischatel townships during the past season, progress is sure to be retarded under the conditions induced by the present laws. There were not over a dozen and a half genuine prospecting parties at work consistently in these two hundred square miles during the past summer, and there was room for four or five times that number. Four-fifths of the land was held idle by speculators. Something should be done to rectify this.

RAILWAY CONSTRUCTION IN THE GOLD BELT

The new branch railway from Swastika eastward through Kirkland Lake to Larder Lake is progressing only slowly on account of some difficult cuts. However, the consensus of opinion seems to be that it will be in operation by the middle of next summer to Larder Lake. Meantime a large survey party has established a winter camp in Boischatel township in Quebec, a few miles east of the interprovincial boundary for the purpose of continuing the railway location eastward along the gold belt. Obviously it is the intention of the railway commissioners of the Ontario government to push the line eastward, under the warrant of their federal charter, as far and as fast as the development of new mines eastward along the belt will warrant it.

At the present terminus of active construction at Larder Lake the two mines of Associated Goldfields and Crown Reserve are progressing very satisfactorily and each has a force of about seventy-five men at work. The old Associated mill has been dismantled and the equipment and material have been moved up to a new mill-site near the new mine. There is not sufficient equipment for a complete mill, but it seems quite feasible to complete it and put it in operation without waiting for the railway to come through. It does not seem likely that the Crown Reserve will bring in material for a mill before the aid of the railway is available.

Before the railway is completed to Larder Lake underground work and diamond-drilling at Lake Fortune and the Noranda property will have showed whether or not these two will make mines. If the deposits show up underground as they do on the surface, the extension eastward of the railway will be well warranted, and no doubt it will be commenced immediately. There is a fairly easy avenue of approach to Lake Fortune from Larder, and beyond that the clay belt makes easy work for the locating engineer

Meantime there is a double inducement for the northward extension of the Canadian Pacific Railway branch from the Quinze dam, its present terminus. There is fine agricultural land all the way from there to the finds in Boischatel and Rouyn townships, in addition to the traffic that promises to develop from the prospective mines. The next year may see the two railways under construction to the heart of the Quebec gold belt and there appears to be sufficient reason for both.

SOUTHERN ALBERTA OIL PROSPECTS

Elsewhere in this issue we publish an interesting and instructive article on Oil Prospects in Southern Alberta by Dr. M. Y. Williams.

Dr. Williams and E. J. Whittaker commenced last summer for the Geological Survey a rather detailed and comprehensive geological investigation and mapping of the southern part of Alberta and adjacent parts of Saskatchewan and British Columbia between the international boundary and latitude 52 deg. Even with these two officers collaborating the field is so large that it will take one, if not two seasons, to com

plete and issue the map and full report. It has, therefore, appeared desirable to issue some interim statements such as the one we now publish, especially as a considerable amount of drilling for gas and oil was being carried on in the area last summer and may be continued next summer.

"THE PHILOSOPHY OF ROCK CRUSHING"

Professor N. E. T. Haultain Is In United States Lecturing On The Above At Several Colleges And Before Bodies Of Mining Engineers

At the request of the American Institute of Mining and Metallurgical Engineers, Prof. H. E. T. Haultain, head of the Department of Mining and Metallurgy in the Faculty of Applied Science and Engineering, University of Toronto, left on the 11th November to deliver a number of lectures in several colleges in the United States on the "Philosophy of Rock Crushing." Prof. Haultain has also been speaking before bodies of mining engineers and others, and has been getting great receptions.

Work Accomplished

With the assistance of Prof. F. C. Dyer of the Department of Mining Engineering and a number of graduate students, Prof. Haultain has, for the past three or four years, been making an intimate study of the tube mills used in rock and ore crushing operations. Through the use of specially constructed laboratory apparatus and the ultra-speed moving picture camera Prof. Haultain and his associates have been able to obtain valuable information concerning tube mills.

The American Institute of Mining and Metallurgical Engineers became interested in Prof. Haultain's work during a visit to Northern Ontario last summer, when they were shown a set of motion pictures made in the Department of Mining Engineering illustrating the movement of balls in a tube mill. In a letter to Hon. Charles McCrea, Minister of Mines for Ontario, the Secretary of the institute, F. F. Sharples of New York, expressed the opinion that the results of this work made one of the most valuable additions within recent years to technical knowledge of crushing machinery.

In Pittsburg Today

Later Mr. Sharples invited Prof. Haultain to deliver lectures on his researches under the auspices of the Institute. On receiving a favorable reply he made arrangements for meetings to be held at Ohio State University, Columbus, Ohio; the University of Pittsburg, Pittsburg, Pa; Pennsylvania State College, State College, Pa; Lafayette college, Easton, Pa; Lehigh University, Bethlehem, Pa; Columbia University, New York City; Yale University, New Haven, Conn., and the Massachusetts Institute of Technology, Cambridge, Mass. In Pittsburg where Prof. Haultain will speak today, addresses are to be given not only to the students of the University School of Mines, but to the students of the Carnegie Technical School, and a third meeting, composed of the Pittsburg section of the Institute and the Engineering Society of Western Pennsylvania.

Value of Camera

The investigations made on rock-crushing in the Department of Mining Engineering, instituted by Prof. Haultain, were first directed to the paths of balls in tube mills. The tube mills, in which all ore and cement is ground fine, consist of a large steel barrel from four to twenty feet long. They are half-filled with Danish pebbles, steel balls or steel rods, and the material is either wet or dry. The work was begun by taking a series of 500 still photographs and later the ultra speed moving picture camera was used, slowing the motion down one eighth on the screen. This produced excellent results.

Research work on the big machines, while still continued, was found difficult, and quantitative experiments were made with small laboratory apparatus, with more rapid results.

Further Tests Being Made

An elaborate series of tests are being made on the actual energy required for the crushing of different types of rock with a set of miniature rolls working in high-grade ball-bearing and connected with a sensitive integrating dynamometer. The necessary funds for this apparatus were provided by the Honorary Advisory Council on Scientific and Industrial Research, of Ottawa, special chrome steel and manganese steel rolls provided by Sir Arthur Hadfield made it possible to study the wear of these and other alloy steels.

The ultra-speed camera was also used to take photographs of the actual crushing of different varieties of rocks.

Prof. Haultain has had nearly 20 years' experience in mining in Europe, South Africa, the Western States, British Columbia and Ontario, previous to taking up academic work some years ago.

WASTE AND WANT

The terrific waste of the World War is largely responsible for high prices throughout the world, and want and starvation in many of its parts. Waste, no matter what its cause, in proportion to its amount, has the same effect upon general prices. It is estimated that the bituminous coal strike caused a loss of over $2,000,000,000 as a direct loss to the miner, operator, the railroads and the consumer. Whether this estimate is correct or not as to the direct loss there can be little question that the indirect loss to the nation is fully as great if not greater, than the loss to the parties who are directly concerned therein.

Wages are usually paid in money. Money is the medium of exchange. The value of the money received in wages to the wage earner depends entirely upon the amount of commodities which he can purchase therewith. If this loss is spread among the 100,000,000 people of the country, it will mean an average loss of $20 to each man, woman and child in the United States. If assumed by the coal miners themselves, it will be a loss of $2,600 to each individual coal miner.

In the end, the fact must be recognized that the more labor produces, the more it can have, and that higher wages, no matter how high, will be of no value to the wage earner, if production costs are increased in the same ratio that wages are increased. - Mining Congress Journal.

German Market For Canadian Minerals

An interesting article has been forwarded to the Trade Department at Ottawa on the German market for Canadian minerals by Trade Commissioner L. D. Wilgress from Hamburg, Germany. The cessation of the industrial boom and the decline in all forms of manufacturing activity caused a marked falling off this year in the importation of minerals into Germany, the report declares.

"The occupation of the Ruhr adversely affected the demand for raw materials by cutting off large consumers from their markets for finished products in occupied Germany. It had been expected that the general resumption of work in the Ruhr following upon the cessation of passive resistance would lead to a great demand for all kinds of raw materials, but the delay in arriving at a satisfactory basis of settlement is retarding business and the position remains very uncertain." The depreciation of exchange also made itself felt.

Refined Nickel

Out of a total import of refined nickel into Germany during the first six months of this year amounting to 895 tons, Canada is shown as having supplied 187 tons, Great Britain 331 tons, the United States 148 tons, and Belgium 134 tons. Consumption of nickel, however, was greatly reduced as a result of the Ruhr occupation and the general decline in business activity.

Canadian Asbestos Best Liked

At present the trade in asbestos is much restricted since most of the factories using asbestos are either closed down or working on short time. Some asbestos imports are sold to Austria, Hungary and Czecho-Slovakia, chiefly short fibred material for making shingles. The report continues:

"The asbestos consumed in Germany is chiefly long fibre stock for spinning purposes. Canadian asbestos is the best liked and realizes a higher price from other countries. Rhodesia is the next and most important source of supply, and although slightly harder and more brittle than Canadian, the asbestos from this source is in good demand. Russian asbestos has been imported during the past year by the Russian Government organization and regular shipments have been received during recent months."

Canada Far in Lead

Figures of asbestos imports into Germany from the leading sources of supply showing the first six months of 1923 and 1922, show that Canada this year supplied about 55 per cent., 1,699 tons out of 3,080 tons, while last year the Canadian shipments were 2,956 out of 5,198, a decrease this year of about 1,250 tons. The record is as follows:

Six mos. to June 30	1923	1922
Canada	1,688	2,956
Brit. S. Africa	397	822
United States	164	562
Switzerland	2	327
Other countries	818	631
Total tons	3,080	5,198

The increase in imports from "other countries" refers chiefly to Russian asbestos.

81,000 Tons Iron Ore

In the case of iron ore, Sweden supplies over nine times what Canada has done. For the first six months of this year the total imports of iron ore into Germany were 1,548,830 tons of which Sweden supplied 770,520 and Canada 81,514. During the same period last year imports were 2,150,061 tons. The revival of production in the Ruhr will result in large importations of iron ore starting again.

Coal Imports Now Down

The cutting off of supplies from the Ruhr has caused a considerable drop in imports of coal. For the first six months of this year England sent in 7,756,627 tons as compared with 1,526,581 tons for the same period in 1922. A fair amount of business has also been done in coal from the United States and Canada. Lately imports have fallen off owing to lessened industrial activity and shortage of working capital. Prices for English coal ranged around 13 shillings a ton at the port of Hamburg.

British Columbia Copper

The report states that it should be possible to dispose of British Columbia copper to Germany. Of a total importation of raw copper into Germany during the first six months of this year of 50,595 tons, the United States supplied 37,805 tons.

Germany has already been an important consumer of Canadian cobalt which is used to a large extent in the enamel, porcelain and glass industries and also as an alloy in the manufacture of steel.

German Mineral Imports

Following are German imports for first six months of 1923 as against same period in 1922:

Tons	1923	1922
Asbestos	3,080	5,196
Nickel ore	18	164
Raw nickel ore	859	1,165
Silver ore	.....	11
Copper ore	18,541	69,499
Raw copper	50,594	72,670
Iron ore	1,548,883	5,218,293
Graphite	7,975	8,754
Mica, raw	284	402
Molybdenum, etc.	466	792
Coal	15,062,542	2,102,215
Coke	460,581	51,568

INDIAN PIG IRON PRODUCED

A large unit in the Indian iron and steel industry reports its production of pig iron for the three-month period, April 1 to June 30, 1923, inclusive, as 95,750 tons, or 27,980 tons greater than that for the corresponding period in 1922. The output of finished iron for these same three months in 1923 amounted to 36,274 tons, compared with 31,470 tons last year.—U. S. Commerce Reports.

Recent Developments in the Fort Norman Oil Area*

By G. S. HUME

Since the Discovery well was "brought in" in the fall f 1920, fifty-three miles north of Fort Norman on the ast bank of the Mackenzie river, oil men interested in anada have watched keenly developments by the Imerial Oil Company in the far Northwest. The distance rom a source of supplies, combined with the problems f transportation during a comparatively short season f navigation on the northern rivers and lakes, greatly etarded test drilling that would give a basis for opinion n the possible production of oil from this sub-Arctic egion. To ensure the use of the good weather of the arly spring and late fall during which navigation was losed, the Imperial Oil Company left a number of men nder the supervision of driller Angus Sutherland to pend the winter of 1922-23 in the oil field and, due to heir energetic efforts, two wells, previously started, vere finished by the close of the 1923 season.

The 1923 Drilling Campaign

During 1922 "C" camp well on the west bank of the Mackenzie had been drilled to 1,700 feet; but, due to drilling difficulties, it was found impossible to continue his hole. Consequently the drilling rig was moved a short distance and a new hole put down. This new hole gives a fair test of its locality, and many will regret to know that no oil was encountered, although the hole penetrated through Upper Devonian and some distance into Middle Devonian strata. The hole, when drilling ceased, was dry. The other hole completed was on Bear Island, in the Mackenzie about two miles from the Discovery well. In this hole a showing of oil was obtained just above the contact between the Middle and Upper Devonian, but the flow was very small. As was pointed out in the Summary Report, G.S.C., Part B, 1922, page 62, oil in small quantities is to be expected at this horizon and the fact that the well at "C" camp produced neither oil nor water would seem to indicate a degree of cementation more complete than would be expected from studies made at the outcrop on the flank of the Norman range of mountains. In the Bear Island well drilling was carried a considerable distance into the Middle Devonian limestones and was abandoned only after a flow of salt water was struck.

Negative Results This Year

In former articles it has been pointed out that there are porous, brecciated limestones below the Ramparts limestone of Middle Devonian age. In various localities the rock of this porous horizon has a strong bituminous smell; but, as pointed out in the Summary Report already quoted, it seems probable that only under exceptional conditions could this horizon be oil-bearing. However, it is believed to be the container of the salt water struck in the Bear Island well. Thus the only two holes completed in 1923 have given negative results as far as the production of oil is concerned. Both these holes are located down the dip from Discovery or No. 1 well, so that the inference might be drawn that the oil is up the dip. In view of the fact that no water was encountered until well below what is considered as the probable productive horizons, the reason for such a condition seems somewhat obscure from data at hand.

Increased Production of Discovery Well

In an article in the *Canadian Mining Journal*, Dec. 1, 1922, page 816, it was pointed out that during work for the Geological Survey in 1922 a sandstone member 50 to 75 feet thick was found in the Fort Creek shales, this formation now giving the production in the Discovery or No. 1 well. It was thought that this was the "sand" from which the oil was derived. No confirmation of this has been obtained, and although Discovery well was cleaned out and deepened slightly this past summer, no evidence of sand such as might come from this sandstone member was found. It cannot, therefore, be known whether the sandstone member extends from the outcrop on Canyon creek to the Discovery well; but from present developments it would seem likely, from the depth to which drilling has been now carried, that if the sandstone member were present at this location the drill would already have penetrated it. On the other hand, the possible flow of oil from Discovery well in its present state is even greater than it was previously, perhaps as high as 100 barrels per day, and it seems difficult to account for such a flow from a shale unless some fairly coarse, porous member provided a reservoir. As has been already

The "Discovery well" of the Imperial Oil Co. Fort Norman, Mackenzie River District, N. W. T.
(The picture shows the well shooting oil during the attempt to deepen it Aug. 1923.)

shown elsewhere, such a sandstone lense would act as a suitable container for the oil and the pressure in the well which is as high as 250 lbs. per square inch, could thus be accounted for. The only alternative explanation which would account for the facts would be the presence of a minor fold superimposed on the main fold at the Discovery well location. No evidence from the outcrops could be obtained to [illegible] such a fold exist.

Geological Information Gained

The results of the drilling, although negative as far as the actual production of oil, is concerned, are nevertheless valuable from the standpoint of the information obtained. The thickest section of the Fort Creek for-

* Published with the permission of the Director, Geological Survey of Canada.

mation encountered was in "C" camp well. In it, about 1,050 feet below the Bosworth formation a considerable thickness of hard limestone was encountered. Below this again more black shale occurred above the typical Beavertail limestone. In the Bear Island well the thickness of Fort Creek Shale is considered to be 1,300 feet. An interesting feature of the "C" camp well is a much smaller thickness of Bosworth sandstones and shales than occurs at the outcrop of this formation in the Carcajou Mountains to the west, the difference in thickness being accounted for by the erosional unconformity separating the Devonian and Cretaceous. For this reason much more Cretaceous occurs at the location of "C" camp well than was formerly supposed; in fact it is believed the Cretaceous here forms a suitable cover for the retention of any oil in the Bosworth sands, a condition that was not formerly recognized for this location. As the Bosworth formation was considered to be the most favorable oil horizon on account of its porosity and due to the fact that most of the seepages originate from it on the east side of the Mackenzie, the results from "C" camp are not encouraging for further exploration of this formation down the dip. It is thought, however, that drilling sites located on suitable structures on the west side of the Mackenzie would have much better chances of obtaining oil from this formation.

More Drilling Recommended

While the results from these two wells are disappointing, they are not such as to warrant undue pessimism regarding the future of this field. The Discovery well has a stronger flow than ever before, and it is the history of every field that test holes must be put down to find the lateral extent of the oil-bearing horizons. From present information the conclusion might be drawn that the possible oil-producing area will be much more limited than at first thought; but until the conditions at Discovery well are better known it would be unsafe to make any predictions. It was the intention of Mr. Sutherland, the driller in charge of operations for the Imperial Oil Company in the Mackenzie area, to shut off the flow of oil in the Discovery well and put the hole down to the Beavertail limestone. An attempt was made to do this, but difficulties were encountered and the attempt had to be abandoned temporarily.

Surface exposures of rock are so few and scattered in the immediate vicinity of this well that no definite conclusions could be drawn from them regarding any possible local structure that might account for the flow of oil. It is to be hoped either that Discovery well will be deepened or that another hole will be put down close by, so that a satisfactory explanation can be given of the exact conditions under which the oil occurs. Such an explanation would go a long way towards determining the future of this field and would be invaluable in the selection of further drilling sites.

B. C. COAL OUTPUT FOR OCTOBER 1923

The coal production of the mines of the Province of B. C. during the month of October 1923, totals 228,293 tons, an increase over the month of September production of 46,659 tons.

Of the total production for the month the mines on Vancouver Island produced 143,020 tons approximately 63 per cent, and 21,140 tons over the production of last month.

The Nicola Princeton mines produced 22,232 tons which is an increase of 3,254 tons over last Month's production and approximately 10 per cent of the total production.

The Mines in the Crow's Nest Pass District produced 63,041 tons during October an increase of 22,265 tons over last month, and approximately 27 per cent, of the total production.

All the mines in the Province showed an increase over last month's production.

The following figures show the tonnages produced by the different Collieries.

Tonnages for October 1923.

BROKEN HILL PROPRIETARY

At the recent annual meeting of the Broken Hill Proprietary Company in Melbourne, Australia, it was stated that, since the mine dumps now being worked over were nearing the end, underground mining would be resumed shortly. There are 954,000 tons of ore reserves. The cost of mining will be heavy, as an arbitration award provides for only 27½ hours of work per week at the face and eliminates the night shift. The Company's principal operation now is the large steel works at Newcastle, New South Wales, where operations were resumed recently. In this case arbitration of disputed points failed of success, and it was a consultation of employers and workmen that finally resulted in renewed activities. The works are on a large scale, consuming about 800,000 tons of coal a year. Coal iron ore and limestone are available under favourable conditions, and Australia is assured of a prosperous iron and steel industry provided her workmen will work.

Vexatious Customs Regulation

Strong Feeling In British Columbia Against Taxation Of Duty on Goods Produced In Eastern Canada And Shipped To West Via New York and Panama Canal

Strong feeling prevails in British Columbia with regard to the exaction of duty on goods produced in Eastern Canada and shipped to Western Canada via New York and the Panama Canal. The agitation gained momentum, it will be recalled, when the Hon. John Oliver, Premier of the Province, directed attention to the collection of duty amounting to several thousands of dollars on a shipment to the Pacific seaboard of steel rods originating in the Province of Nova Scotia. Reference was made to this matter by the *Canadian Mining Journal* and the demand that British Columbia then made that a Canadian Customs Official be placed at New York in order that Canadian goods might be shipped to the west via that Port in bond was made the subject of favorable comment.

On the 15th November last the Hon. Mr. Oliver made a statement to the Legislative Assembly of British Columbia in support of a resolution standing in his name and demanding the abolition of the anomaly of an interprovincial tariff and to facilitate this that a customs officer be appointed by the Dominion Government for duty at the Port of New York. The resolution went the length of giving the Province authority, in the event of the necessity arising, of making a test case of the point of the legality of the collection of the duty described, it being the opinion of Premier Oliver that the Dominion Government would be unable to sustain its position under the terms of the B. N. A. Act. The Premier, however, softened the harshness of the resolution by the explanation that it was not expected that the Government would be compelled to go to extremes. It is significant that, subsequently, the Hon. Jacques Bureau, Minister of Customs & Excise, caused it to be publicly announced that he is prepared to recommend that a Customs Officer be stationed at New York. It appears, therefore, that the dispute is to be amicably settled.

The statement of the Hon. Mr. Oliver, however, is interesting as it fully recites the circumstances of the case in question and is a striking illustration of the transportation developments that have been taking place since the opening of the Panama Canal a few years ago. He said:

"In supporting the resolution now before the House I wish to do so absolutely free from any tinge of partisan politics," the Premier declared, in a written statement which he read to the House. "To my mind the question is one of Provincial rights under the Constitution pure and simple, and as the customs regulation which is being called in question is one that has been in force apparently for a number of years, and has been effective both under Liberal and Conservative administrations so that both political parties may reasonably be held equally responsible, that fact alone, I think, should be sufficient to remove the matter from any question of partisanship.

"I think a short simple statement showing how this question came before the Government may be in order. This matter was first brought to my attention when in Ottawa in January last by J. B. Thompson, president of the Vancouver Board of Trade. When I was told that the Dominion customs authorities were collecting duty of steel rods manufactured in Nova Scotia I could scarcely credit the information. I was, however, shown a letter signed by R. T. Farrow, Commissioner of Customs at Ottawa, addressed to Mr. Thompson, from which I quote as follows:

"'I return herewith copy of letter from Mr. McDougall to the secretary of the Board of Trade, Vancouver, which you left with me this morning, respecting the collection of customs duty at Vancouver on 550 tons of wire rods shipped from Sidney, Nova Scotia, to New York by the Dominion Iron and Steel Company, and there transshipped by vessel to Vancouver.'

"Again I quote from the same letter:

"'No Canadian Customs officer stationed at New York for the purpose of supervising shipments of this character and certifying to manufacture. This Department has no power under the law to admit goods shipped in this manner free of duty.'

"I quote from the letter of Mr. H. H. McDougall as follows:

"'The Dominion Iron and Steel Company, of Sydney, Nova Scotia, in October last shipped 550 tons of wire rods by steamer to New York, there connecting with one of the Canadian Robert Dollar boats to Vancouver, through routing being arranged before the shipment left Sydney. On arrival here on the 27th of December, the Collector of Canadian Customs demanded and forced payment of $3,512.52 duty and sales tax, and which was paid under protest. Strong appeals were made to the Department at Ottawa, but without avail. Without adding duty and sales tax we could have purchased these rods from Belgium for $11.00 per ton less, or $6,050 on the shipment, and with customs charges makes the difference $9,562.00.'

Ottawa Astonished

"I brought the matter to the attention of both Premier King and the Hon. W. S. Fielding, Minister of Finance, and both gentlemen expressed their astonishment at the facts disclosed. On my return to Victoria I again took the matter up with Premier King, forwarding him copies of both Mr. McDougall's and Mr. Farrow's letters, and particularly directing his attention to Section 121 of the British North America Act. Again on April 26, 1923, I wired Premier King more directing his attention, not only to the matter of steel rods but also to asbestos mined in Quebec and shipped to Vancouver via New York and upon which customs duty was collected upon arrival at Vancouver. I also drew attention to the advice received by salmon canners, that canned salmon destined for Eastern Provinces, shipped through the Panama Canal and transferred at New York

would upon re-entering Canada, be subject to customs duties.

In July last I was advised by the Premier's private secretary that an Order-in-Council had been passed on the 5th instant directing the refunding of the duty on steel rods. It does not appear, however, that collection of customs duties on Canadian made goods has ceased.

"In regard to the duty on asbestos I have a letter from Taylor, Forbes & Co., of Vancouver, dated April 16 last, in which they say:

" 'Asbestos cement, which, as you know, is mined almost entirely in the Province of Quebec, can be purchased from the Canadian Asbestos Company at their mines, shipped to New York by rail, transshipped there and brought around through the Panama Canal to Vancouver. In order to do this it is necessary to pay a duty on the material coming back into Canada of 25 per cent. In spite of this fact it can be laid down in Vancouver by this route for about 40 cents per sack of 100 lbs less than if it is brought direct from the mines to Vancouver by either of the transcontinental railway lines.'

"I have also a letter from the Canadian Asbestos Company of Montreal dated March 15 last, from which I quote as follows:

" 'For your information we might state that we ship our asbestos cement via New York and pay duty on the same entering Canada again, and we can lay it down in Vancouver $6.75 per ton cheaper than if we shipped it all rail through Canada.'

"Further on in this letter they say:

" 'It is only recently that we succeeded in getting the railways in Canada to give us a rate of $1.32½ per 100 lbs. The rate last year from Thetford Mines to Vancouver was 1.57½ per 100 lbs.'

"I next refer you to the Hansard report of March 16, 1923, where Mr. Ladner, M. P., asked if the Government had refused to place a Customs Officer at New York, and the answer thereto given by Hon. Mr. Bureau is as follows:

" 'An application has been made to place a customs officer at New York to look after the traffic that goes via the ocean and the Panama Canal. This matter has been under the consideration of the department, and while the department has not decided definitely, it feels inclined to refuse the application, because this would divert traffic towards the United States and all the Canada railways would get out of it would be the haul from the point of departure to the boundary—the whole of the railroad haul to the sea and the whole of the ocean freight would go to the United States.'

In Interest of Railways

"I think the only construction to put upon this statement of the Minister of Customs would be that the customs regulation which requires duty to be paid on goods transshipped at New york, or any foreign port, was made primarily in the interests of the railway companies. This view is further confirmed by a letter from the Honorable the Minister of Customs to the secretary of the Vancouver Board of Trade, dated May 1, 1922, which reads as follows:

" 'I am in receipt of your letter of the 19th ultimo, referring to a delegation from your board which waited upon me some time ago respecting the assignment of a Canadian customs officer to duties at New York in the supervision of transshipments of Canadian goods forwarded to British Columbia from points in eastern Canada and vice versa. I find it has always been the policy of all governments to decline to entertain applications for this service, and after careful consideration of the matter, I have decided to take the same view of the question, believing that the granting of the application is not in the general interests of the Dominion in view of the great expenditure incurred in constructing transcontinental lines in Canada.'

"I think it is quite easy to see from the last sentence quoted that the dominating influence opposed to the establishment of a customs officer at New York is the interests of the transportation companies.

Start Shipping Line

"When in Ottawa in August last I again took up the matter with the Minister of Customs and was advised by him that arrangement had been made whereby a line of merchant marine would ply between eastern Canadian and western Canadian ports. The steamer Margaret Coughlan was then in process of loading for Vancouver, and the owners of this vessel appeared to be strongly opposed to the appointment of a Canadian customs officer at New York as being inimical to their interests, possibly even to the extent of preventing their venture from being a success. I must admit that the arguments used made some impression upon my mind, and I communicated with the Vancouver Board of Trade on the subject. However, I found the board did not take the same view as the Minister of Customs, and decided in favor of continuing to press for the establishment of a customs officer at New York.

Urges Appointment

"On September 6 last, I again wrote to the Minister of Customs urging the appointment of this officer, and when the Minister was in Victoria recently I further pressed upon him the necessity for appointing this official, and also for the discontinuance of what, to me at least, appears to be an allegal practice of collecting customs duties on Canadian goods. More recently I have received a copy of letter forwarded by Dingwall, Cotts & Co., agents for the owners of the Margaret Coughlan, dated November 6, and addressed to the Minister of Customs in opposition to the appointment of a customs officer at New York. I also personally received a letter from Dingwall, Cotts & Co., dated November 3, from which I quote as follows:

" 'We beg, however, to place before you our opinion, that the appointment mentioned would be of very little, if any, benefit to Canadian interests in comparison with the harm done to other lines of Canadian activity, principally those of railroading and shipping.'

I am glad, however, to state that Messrs. Dingwall, Cotts & Co. have changed their views considerably, and in a letter, dated November 8, directed to the Minister of Customs, they say:

" 'These facts alter our views considerably, and under the circumstances we would not oppose the appointment of a Canadian customs officer at New York.'

Contrary to Act

"I think I have shown fairly conclusively that there is in existance a customs regulation imposing duty on Canadian goods moving from one part of Canada to another part of Canada, if it so happens that such goods in transit are transshipped in foreign territory. I think

I haveI have shown that this customs regulation has been framed in the interests of transportation companies, particularly railway transportation companies. I have shown that in one instance the duty collected has been refunded. I think I have shown that the imposition of this duty is contrary to Section 121 of the British North America Act, and in this I have the opinion of Mr. A. V. Pineo, who says:

"'This section is found under a group heading with other revenue clauses which clearly extend to Federal legislation. I am of the opinion that so far as customs duties are concerned it would operate to restrict Federal legislation as well as Provincial.'

"I construe this opinion of our legislative counsel to mean that the Federal Parliament has no power to override the very clear wording of this section of the British North America Act.

Will Aid Suit

"Notwithstanding all the representations made to the Government at Ottawa on this matter, I am advised that a large department store in Vancouver has a large consignment of Canadian made goods in transit from Toronto via the City of New York and the Panama Canal to Vancouver. These goods will be subject to Canadian cutoms dutis and I wish explicitly to draw the attention of the House to the wording of the Third Resolution in the motion now before us, urging upon the Provincial Government to take such steps as it properly may to resist the imposition of customs duties upon Canadian products and manufacturers destined to British Columbia, or produced or manufactured in British Columbia and destined to any other province of Canada.

"If the House agrees to this Resolution it will mean that the Government will become a party, if necessary, to a suit resisting the demand for the customs duties referred to. I sincerely hope, however, that better counsels will prevail with the Federal Government, and that the whole matter may be amicably adjusted. In fact I may say that I have strong hopes that such will be the result, and I believe that the passing of this motion by a unanimous vote of the House will materially aid in bringing about the desired event."

Ventilation in Cape Breton Collieries

Ascensional System Now Being Organized in Collieries of the Dominion Coal Company

By JOHN MOFFATT

Two years ago it was decided to place all the Dominion collieries under the ascensional system of ventilation. Lying on an angle of inclination to the horizontal varying from eight to twenty degrees, all the Cape Breton coal seams readily lend themselves to this system. For with the main currents led direct to the faces through intake airways as the size of the mine necessitates, it is usually an easy matter to lead the air back into the returns when expanded by the higher temperature of the mine, and made still lighter when diluted with methane. The main return airways are constructed to carry the air to the upcast shafts, permitting a sufficient quantity to escape through the waste workings to keep them clear of gas.

In opening up a new colliery adapted to ascensional ventilation the system would be simplicity itself. But to change to this from some other system in collieries that have been in continuous operation from fifteen to forty years is a big task. It has been so at these collieries and it has called for large expenditure; but these will be more than repaid when the work is completed, which should take place within the next few months at most of the collieries. In a few it is already completed.

Old Systems Inadequate

The airways of the early collieries of this and other mining districts have not always been given proper attention. Here and there a manager might be found who gave ventilation its rightful place in his management of the mine, and, if permitted, the aircourses were well kept. But usually these had only secondary care and were not so large or so clean as necessity required. This was not always due to carelessness; more frequently it arose from the want of a broad policy on the part of the small operator, who failed to calculate the life of the colliery. Usually small concerns have small policies and do not lay their plans on a large scale. This is true everywhere, and Nova Scotia was no exception. Therefore when a survey of the main airways of the Dominion collieries was made, it was fround that about thirty-three miles iof the main aircourses had to be repaired and remade. This was referred to over a year ago in the **Canadian Mining Journal.** Reference was also made to the tremendous amount of labor involved in cleaning, timbering and enlarging these airways, while giving attention to their extension as the mine developed.

Plaster Stoppings Economical

The fan runs had first attention, and, being usually built of concrete, were reinforced and put into first-class condition. Then the down-cast shafts were examined and all water that might form ice in winter and so block up the air passage was drained off. Strong concrete stoppings were built in the main intake airways. In many cases a second intake airway was added, which greatly increased the volume of air passing into the mine and reduced the water gauge. Stoppings in the secondary airways were built of hard wall plaster and were carried close up to the faces. It took some time to discover that the shock of a heavy shot going off affected the plaster stopping, but this was remedied by a new method of construction.

At first it was thought that stoppings built of logrods and hard wall plaster would be much more costly than brattice stopping, but experience has proved that this is not the case. Brattice cloth exposed to strong currents of air in the mine soon dries up and if not renewed becomes practically useless for ventilating purposes, as the air passes through it too readily, and is not conducted as intended. On the other hand plaster stoppings when properly built last indefinitely and

have little leakage. The first costs are about the same, but the cost of upkeep and replacement of the plaster stopping is very low compared to that of brattice. To this has to be added in the case of brattice the labor of constant examination.

Reduced Power Costs

It was further stated by the *Canadian Mining Journal* that the ascensional system of ventilation would not only largely increase the volume of fresh air at the faces, but would lessen the power costs. This has been fully demonstrated at one of the collieries, where the volume of air entering the mine in 1901 was 100,000 cubic feet but is now reduced to about 30,000 cubic feet per minute; yet a larger quantity passess through each split, and each section is fully supplied with fresh air. The power used in this case is only one-third of what it formerly was. In other words, with only a 50 per cent reconstruction of airways there is a two hundred percent improvement. This is a remarkable increase in ventilation efficiency, and is accomplished by a fan which, but for the enlarging of their airways, would have been scrapped in favor of a new one.

Small Fans Now Adequate

There is another factor to be considered in the item of expense—that of the fan. Small, badly obstructed airways offer great resistance to air currents, and when these fail to supply the sufficient quantity of air the old fan is usually discarded and a new and larger one purchased. This costs money as, in addition to the purchase price of the fan, there is the additional cost in power necessary to drive it. Large, well kept airways increase the life of a fan and lower the costs.

The change that has already taken place in the airways of the Dominion collieries has extended the life of the fan to the full life of nearly every one of the collieries, and has reduced the annual increase of the water gauge by half. That is, the increase of water gauge, which each year under the old system was about 2.4 inches, due to airway extension and added friction, has been reduced to 1.2 inches. As a fan at a colliery must be in continuous operation, is seldom slowed down and then only for a short time, and must be supplemented by an auxiliary in case of accident, the saving from this source alone is large.

Mine Gas Well Diluted

Again, the amount of methane in the mine atmosphere has been greatly lessened by much more rapid dilution. What this means to the safety of the mine is readily understood by all who take the percentage of methane in the return airways as an indication of the true condition of a colliery giving off gas. A large percentage of methane in the mine atmosphere is not only dangerous but prevents the rapid development of the colliery, which again tends to increase the quality of gas driven off. Thus a well ventilated mine could if required, be placed on double or treble shift, while it would be impossible in a heavily methane laden atmosphere to operate more than one shift in the twenty-four hours.

An investigation now taking place into the cause of an explosion in Britain has as its chief feature the quantity of methane reported by the inspectors of that mine. The lowest amount was said to be about 4 per cent. Two and one-half per cent. of methane in mine air is close to the danger point, and it is the aim in the Dominion collieries to keep below this point.

Warning Against a False Sense of Security

When the new system is put into full operation in the Cape Breton collieries, it may be found difficult to persuade some of the mine managers to reduce the speed of the fans, fearing a reduced quantity in the volume of air reaching the faces. But it will be fully demonstrated that all fears are groundless and that although the amount of air entering the mine may not be quite as large as formerly, yet by more equal distribution, better conducted air currents, and a greatly reduced loss by leakage, the volume reaching the faces will be largely increased. However, in order that the system should give the expected results, the present practice of keeping all crosscuts, except the one nearest the face, closed should be maintained. Should a reliance on the larger quantity of air circulating in the different air splits stimulate the feeling of security and lead to neglect of the proper conducting of the air up to the faces, then an element of danger and not of safety may be introduced. This will not be so in the Nova Scotia collieries, where mine officials are usually well trained and attain to their positions by ability and a proved capacity to handle their collieries.

To sum up, the net gain of the ascensional system of ventilation is (1) greater safety of the mine through more rapid dilution of the mine gases; (2) improved working conditions for mine workers through separate fresh splits for each district; (3) lower temperatures in the inner workings; (4) increased volumes of air with reduced power costs; (5) lower depreciation charges due to prolonging the life of the fans, with a lessened expenditure for new machines.

LOW-FREEZING EXPLOSIVES

In the old days, when nitroglycerin dynamites were in general use, many quarry and mine operators at this time of year were making necessary repairs on the dynamite thawing house, in preparation for the coming winter. The thawing of explosives was usually a troublesome operation and, when improperly conducted, a dangerous one.

The development of gelatin and ammonium nitrate dynamites in which nitroglycerin is replaced by, or combined with, other explosives and low-freezing ingredients, has practically eliminated the necessity for thawing; it is only in exceptionally cold climates that any difficulty remains.

Explosives chemists have never been able to say definitely at what temperature a certain explosive will freeze, because freezing depends upon the length of time that the explosive is exposed to cold as well as upon the temperature; in other words, a low-freezing explosive is one that is slow freezing. After years of experience and experiment, there have been developed ammonia and gelatin dynamites that are so slow-freezing that they can be considered practically non-freezing. The other desirable features which distinguish ammonia and gelatin explosives are retained in the low-freezing grades. This transformation has been so effective that manufacturers are eliminating the old high-freezing grades; one company will now supply them only on special order. Some brands of low-freezing ammonia and gelatin and permissible dynamites are so slow-freezing that they are being used in most sections of the country on open work all through the winter, without thawing.

Enquiry at Springhill Collieries, N. S.

The Questions of Bumps and Bottom Coal And the Occurrence of Accidents

Because of the number of bumps and the recurring loss of life from this cause in the Springhill collieries, Deputy Minister of Mines, T. J. Brown, was instructed by the Minister to make an enquiry at Springhill with the view of determining the cause and making recommendations to avoid bumps and lessen the number of accidents. This was a big order, to use a street term, but it was carried out in a manner most satisfactory to the workmen, the Coal Company and the other members of the Mines Department. A very searching investigation was made, evidence being taken in the mine and at meetings of the workmen called for the purpose. Other meetings were held in Halifax to weigh the evidence and devise means to prevent or lessen the number and force of the bumps.

On the committee were Daniel Matheson, D. Ross and T. A. Bonnyman representing the employees, all three men having had long experience in mining coal in Springhill Mines. Messrs. W. Herd, Chief Mining Engineer of the British Empire Steel Corporation. T. L. McColl, Mining Engineer of the Acadia Coal Co. an Malcolm Blue, Superintendent of Mines, B. E. S. Co. mainland collieries; Messrs. E. B. Paul Deputy Inspector of Mines Cumberland Co., R. H. Gray Inspector of Mines for Pictou Co. and Thomas J. Brown Deputy Minister of Mines for the Province.

Much interest was taken in the work of the Committee as there was much anxiety and alarm in the minds of workmen because bumps continued to occur and take away life in an instant.

The discussions were marked by an earnestness and freedom of expression such as the case required and each member labored to arrive at a solution unbiased by any personal prejudice.

It was agreed that the evident cause of such serious and sudden disturbances lay in the nature of the roof and pavement. The roof overlying the coal is very strong. Thirty feet of this gives way first and above it is a very strong sandstone. Left without support this great span with its enormous weight exerts pressure at certain points on the pillars which cannot bear it up and suddenly gives way, throwing down great masses of coal with tremendous force and suddenness burying everyone and everything in its way. Even when the pillars are solid and thick enough to resist its pressure the pavement has been found to give way and open and rise as if pushed upwards with some stupendous force, hurling tracks in all directions and displacing timber like so many matches.

When these sudden settlements of the arched roof take place in the pillar workings, or in the waste, the resistance is low hence there are very few accidents, but the earth tremors caused by the settlement is more widely felt on the surface than a more dangerous bump in the vicinity of the working places. As the collieries become deeper the danger increases owing to the greater weight of the superincumbent strata.

The method of mining was first discussed more especially the mining practice at the face. The width of the working place, the thickness of the pillar and the system of timbering were reviewed. The distance between the balances and the length of the boards came under fire and changes were recommended which place the width of the board at ten feet and the distance between balances one hundred and fifty feet. The pillars are to be left thin so that they can be rapidly extracted thereby quickly relieving the pressure. It is generally thought that work should be concentrated in small areas, bords should be rapidly advanced and pillars drawn at once. At such depths as 22,500 feet there should be no old workings resting on pillars, as such practices lead to loss of coal and to bumps, also squeezes.

The fine diplomacy of the Deputy Minister of Mines is seen in that part of his report dealing with balance measurements when he says —"It was generally admitted by all that the older these working balances are, the more dangerous they become in the event of a bump. The longer it takes to drive in the rooms the less pillars there are to take out. If a room is a long time in driving and is going ahead slowly, both nature and human nature are busy nibbling away, with a resultant wide room and narrow pillar and when sudden pressure comes there exists a dangerous situation. Most men would have said that the filling away of the coal falling off the sides by the miners was a dangerous practice, but Deputy Minister of Mines T. J. Brown, knows the temptation of a loose pile of coal lying on the road side and admits that it is only human nature "to nibble" at it now and again, although that very nibbling may invite disaster. He knows also that gentleness makes great and he knows the miner as few other men do and therefore he gently leads.

The most difficult of all the problems was that of the practice of leaving some coal on the bottom at the low side. This custom is as old as the Springhill collieries.

Bottom Coal

The practice of leaving some coal on the bottom at the low side of the room proved to be a more serious matter and more difficult of solution. The Company's representatives contended that this was an unsafe practice as the low side timber was placed on this coal and as a result was not firmly set and in the event of being submitted to pressure would penetrate the coal and be of no use. And further that the coal weathered or softened and the low side timber became loose and useless. They contended that the feet of the timber should be in the solid stone not touching coal in the bottom or low side in order to be effective. They also contended that if the pillar moved or the bottom nugged or kicked as the result of pressure that if the timber is on bottom coal it is more likely to [illegible] men at the working face.

On the other hand it was contended by the miners that leaving in the bench coal on the low side was the safest [illegible] firm enough to withstand this pressure as witness the props being cut into the booms which would indicate their feet were firmly set. They also contended that the base of the prop was less liable to be kicked out if it rested on the "footwall" of coal and it was strongly argued by the men that where the pillar moved towards the centre of

the room, as they often do, that the bottom coal also moved and the timber is not tripped out.

It was also contended by the workmen and others that this footwall was a protection to the miners as the pavement was not so liable to 'open up' if the coal was left there.

However the strongest contention put up by the miners on this question was that when the bottom was left on the low side and at least the low side rail of their road resting upon it that there was a feeling of greater safety to the men loading coal and mining on the low side in the event of an outburst of coal either from the face, high or low side, as the miner was not down in a hole and had a greater chance to escape.

Some miners in the mine seat their lower side props in the bottom, this from choice. Others, and they are in the majority, seat the timber on the coal and men with 30 to 40 years experience in mining feel so strongly that the footwall is safer they would leave the mine were they forced to dig up the low side bottom. In the event of bumps the low side timber has been thrown out with about equal regularity whether seated on the stone pavement or on the coal.

Commenting on this discussion Deputy Minister, T. J. Brown states that the Company's contention in general mining practice is sound. He was inclined to favor the view that conditions exist in Springhill that make exceptions. The Company officials in Springhill are not all of the same opinion in this matter. The officials on our Committee were unanimous in favor of going down to the stone. The workmen's representatives were strongly and unanimously opposed. Mr. Paul favored the workmen's view, Messrs. Gray and Brown were not sufficiently acquainted and had not the local experience necessary to form an opinion of value. The many experienced workmen who so unanimously and emphatically were opposed to taking out the bottom coal on the grounds of personal danger to themselves, and my belief that no selfish motive prompts them to this attitude, forces me to the conclusion to leave this question where we found it, viz., a question of arrangement between local management and workmen, to be decided by conditions as they find them in the working places.

The Minister of Mines and his very able Deputy Minister are to be commended for the prompt action taken and the wisdom shown in inviting all parties directly interested to a joint discussion of this very serious problem and the recommendations made and put into practice will be watched with eager interest by the whole Province.

SILVER AND ITS ALLOYS

Research Will Probably Reveal New Uses in Commerce and Industry

Systematic study of silver and its alloys should result in its wider use in at least two fields, with strong probability of similar results in other directions, according to a report submitted by the U. S. Bureau of Mines to Secretary Work of the Interior Department in response to his recent request for a preliminary study of possible new uses for silver in commerce and industry. The possibility of developing a non-tarnishing silver for use in tableware and the arts and of finding silver alloys suitable for trimming automobiles were set forth as the two fields in which a systematic investigation should result in a wider use of silver.

"Silver has been allowed to fit into places where i would satisfy the requirements, and little systemati research to develop new uses has been done," the Burea of Mines' report stated. "Such research, therefore, ha a better chance of success than if the field already ha been extensively investigated. Although individual pr ducers and fabricators have not overlooked the possil ities of such studies, it is believed that the situation n has reached a stage where, under governmenta: dire tion, these individual investigations could be co-ord nated into a systematic plan of research to increase th commercial and industrial use of silver.

"One of the major possibilities would be through t development of new alloys. It is well known that small percentage, in many cases only a fraction of per cent, of one metal alloyed with another changes t properties of the latter greatly. Everyone is familia with the decided change in appearance caused in copp by the addition of a small percentage of nickel, as w as with the decided change in properties of steel caus by the addition of very small percentages of non-f rous metals. It is entirely possible that a systema investigation would develop alloys or silver which woul have most desirable properties for use industrially commercially.

"One of the chief drawbacks to the use of silver household articles is that it readily tarnishes. If th could be overcome or materially decreased by means the development of an alloy which would not be exc sively expensive, it should result in a great increas in the use of silver articles and, in turn, in a large i crease in amount of silver consumed.

"It is known that certain metals, including cadmiun when alloyed with silver reduce its susceptibility t tarnish. This is mentioned merely as an example. I is entirely possible that other metals or combinatio of other metals with silver would form an alloy le susceptible to tarnish, if not non-tarnishable, unde ordinary conditions.

"There is further the possibility of developing r latively cheap alloys in which only a small proporti of silver will be used which, due to the large consump tion of such alloys, would result in a large increase the amount of silver consumed. Silver-aluminum all deserve consideration in this connection. One of th uses to which such an alloy might be put would be tha of trimming on automobiles. A silver alloy relativ non-tarnishable and solid throughout would have d cided advantages over the present nickel-plated trin The investigation of the possibility of producing suc an alloy is worthy of consideration."

Secretary Work has submitted a copy of this r to Senator Tasker L. Oddie, chairman of the S Commission of Gold and Silver Inquiry, requesting opinion from the commission as to whether the publ interest would warrant the Interior Department u taking the co-ordination of individual investiga and the beginning of a systematic study of new u for silver.

IRON AND STEEL PRODUCED IN SOUTH AFRICA

During the year 1922 three iron and steel plants were in operation in South Africa, giving employ to 1,080 persons. Two plants were not producing The Department of Mines and Industries reports that 1 tons of iron and steel were produced during the y of which 2,090 tons were from electric furnaces. Th total output for the year 1921 amounted to 22,475 tons —U. S. Commerce Reports.

Discovery of Bauxite in B. C.

Deposits Located Near Stony and Demaniel Creeks Reported on By Government Mining Engineer

By ROBERT DUNN

The discovery of Bauxite in British Columbia has been reported on several occasions. Investigation, however, has shown that the material thus far found is not sufficiently high grade for purposes of aluminum manufacture. Recently deposits were located near Stony and Demaniel Creeks, Sooke District of Vancouver Island, of such extent as to warrant their inspection by Wm. M. Brewer, the government mining engineer. His report is to the effect that they contain a low grade of bauxite, the analyses of a representative assortment of samples indicating that the ore is so low, comparatively, in alumina and high in silica or insolubles as to obviate the possibility of it being useful for the production of aluminum. Owners of the claims, however, have found a market for the material for the refining of gas and are anticipating that with development and experimentation further commercial utilities will be discovered.

Mr. Brewer writes of these Vancouver Island deposits as follows:

"In Memoir No. 96 describing the Sooke and Duncan Map Areas, Vancouver Island, by G. H. Clapp, published by the Canada Department of Mines, Geological Survey Branch, reference is made to ochreous clay or impure bog iron ore in the bed of Demaniel Creek, one half mile south of Young Lake in the Sooke District. This deposit is referred to by Clapp as being adapted for a good base for colored paints but valueless as iron ore on account of the low iron content which Clapp places at 15.5 per cent.

"In the Minister of Mines Report for 1922 this deposit is also described by W. M. Brewer, Resident Mining Engineer of the Western Mineral Survey District (No. 6) and included in the description of the Demaniel Creek deposit reference is made to a deposit of similar material occurring on Stony Creek, a tributary of Demaniel Creek, which may be an extension of the Demaniel Creek deposit.

"The examinations made by both Clapp and Brewer were apparently confined to a consideration of the possibilities of iron making or the manufacturing of paint from the deposit of limonite or bog iron ore, but samples taken from the Demaniel Creek deposit by Victor Dolmage of the Geological Survey of Canada during the fall of 1922 when assayed in the Mines Branch of Ottawa created considerable interest, because the detailed analysis of the ore showed that the mineral approached bauxite more closely than had been previously found in B. C. Owing to this information the deposits on Demaniel and Stony Creeks were re-examined by Brewer and the samples were analysed as samples of bauxite rather than as samples of iron ore.

The results of the analyses of two samples from Stony Creek and two samples from Demaniel Creek are as follows:

Analysis made on the solubility in sulphuric acid

	Loss on Ignition	Insol.	Al_2O_3	Fe_2O_3	CaO	MgO	Ti.
Stony Creek, Sooke..	12.3%	25.0%	29.5[illegible]	30.5	0.4	nil	nil
Stony Creek, Sooke..	13.4	30.7	30.0	23.0	0.4	nil	trace
Demaniel Creek, Sooke.. ..	10.2	62.2	19.0	6.0	2.5	nil	nil
Demaniel Creek, Sooke.. ..	16.0	35.0	29.0	16.0	1.3	nil	trace

Of course the above mentioned analyses show that the samples of the mineral are not sufficiently pure to be used in the manufacture of aluminum. This is very clear when the above analyses are compared with the analyses of bauxite from which aluminum is manufactured in the United States as follows:

Analyses of Bauxite:

Location	SiO_2	Al_2O_3	Fe_2O_3	TiO	Water at 100°	Authority
Alabama	.7	56.60	2.75	2.3	25.30	McAlley; Ala. Sci. Soc.
Arkansas	10.64	57.48	2.56	[illegible]	28.36	Mead: Econ. Geol. Vol. 10. p. 48
Georgia	14.47	54.57	1.93	1.63	[illegible]	Sherer: [illegible] Bull. 31, p. 79.
	8.84	58.38	1.30	1.80	29.25	[illegible] Bull. 31, p. 70.
	10.63	57.91	[illegible]	1.11	28.70	[illegible] Bull. 31, p. 37.
Tennessee	18.38	49.90	4.13		[illegible]	Phalen: U.S. Geol. Sur. Min. Res. 1912, p. 5.
	17.16	53.34	2.10	[illegible]	[illegible]	[illegible]
French Bauxite	2.8	[illegible]	[illegible]	3.1	10.80	Phalen: U.S. Geol. Sur. Min. Res. 1910, p. 8.

Owing to the low grade of the bauxite ore in the deposits that occur on Demaniel and Stony Creeks it became necessary to find some other use than the manufacture of aluminum in order to give the mineral a commercial value.

Almost by accident as it may be termed, such other use was found from the fact that limonite or bog iron was found to be adapted for refining gas, the oxide of iron being used to absorb the sulphur in the gas manufactured on the Pacific Coast. An order for a shipment of the limonite or bog iron ore for use in the Victoria Gas Works was received by Dan Campbell, the owner of the bauxite deposits. In making this shipment he found that the lighter colored clay material became so much intermixed with the iron ore that it was very difficult to separate the two materials before shipment. The Gas Works however reported to him that the lighter colored clay material or bauxite appeared to be as well adapted for refining the gas as the limonite or bog iron ore and as the price paid for the mineral was considerably greater than the market quotations for bauxite ore in the east, it is very satisfactory to have secured a market for the production of the deposits.

In this connection it is gratifying to learn by perusal of an article in one of the leading journals, Journal of Society Chemistry and Industry, that at the new oil refinery erected by the Anglo-Persian Oil Company in Llandarcy, South Wales, bauxite is used in the refining of oil as explained in the following paragraph:

"The kerosene fraction receives its final treatment by means of filtration through granulated bauxite a reddish brown aluminum ore. The bauxite previously roasted, removes the sulphur and color, the oil coming from this process sweet in odour and perfectly colourless, being in fact, the highest grade of lamp oil or kerosene. After a certain period of use the bauxite is re-roasted to burn out the impurities taken from the oil, after which it can be used again."

From the same article it is ascertained that in the extraction of paraffine wax from crude oil, bauxite is also used, the wax undergoing a final treatment of filtration through bauxite to remove the color.

Although the samples taken from the surface outcroppings of the deposits on Demaniel and Stony Creeks up to the present time, show by analysis that the ore is so comparatively low in alumina and high in silica or insolubles, yet it may be encouraging to the owners of the property to also know that samples taken from the Alabama and Georgia deposits when first discovered about 1893 were found to sometimes vary in their contents to such a considerable extent that practically every wagon load mined had to be analysed because at that time no bauxite was considered sufficiently pure to manufacture aluminum unless the ore carried over 52 per cent. Al_2O_3 and not more than 2 or 2 per cent SiO_2.

In addition to being used for the manufacture of aluminum bauxite is used for the manufacture of artificial aluminum abrasives, such as alundum, it is also the chief crude material for the manufacture of various aluminum salts, such as alum, aluminum chloride and aluminum sulphate and is used to some extent in the manufacture of aluminum refractories which are sold as bauxite-brick or high alumina-brick.

It is a question whether the low grade bauxite on Demaniel and Stony Creeks can be utilized in the manufacture of any of the above mentioned articles except bauxite-brick in the manufacture of which the material is used without preliminary treatment other than drying and fine grinding for mixing with other ceramics material for refractory purposes, but the problem as to the uses that the mineral in the deposits on Demaniel and Stony Creeks is one that must be settled by the chemist rather than by the Mining Engineer.

So far as regards the quantity of the mineral in the deposits mentioned it is impossible at the present time to make any other than the wildest kind of a guess, for while it is quite possible that the two deposits are connected and extend for nearly a mile in length with a proven width at one point of upwards 40 feet and an undetermined depth below the beds of both Demaniel and Stony Creeks, the actual prospecting work so far done has not shown that such conditions actually exist, but on the other hand indications point towards the possibility of the occurrence of the mineral attaining such dimensions as above referred to.

PURIFICATION OF COPPER SULPHATE SOLUTIONS

Experimental work on the purification of copper sulphate solutions from the leaching of low-grade oxidized ores is being continued at the Pacific Experiment Station of the United States Bureau of Mines at Berkeley, Calif. Attention has recently been chiefly given to the removal of ferrous and ferric iron from such solutions, together with any aluminum present. The use of powdered limestone, or copper oxide, or natural oxidized minerals of copper, will by hydrolysis precipitate, first, ferric iron, later aluminum, and then copper as basic sulphates. The copper, however, is hydrolysed before ferrous iron, so that it is necessary to oxidize the ferrous iron to the ferric condition before hydrolysis. Work on use of air for agitating the pulp during hydrolysis and for oxidation of the ferrous iron showed that at the acidities of solution where ferric iron and aluminum were precipitated, the ferrous iron was slowly oxidized and the resulting sulphate immediately hydrolysed. By further lowering the acidity by adding more limestone, copper oxide or other hydrolysing agent, the speed of oxidation of the ferrous iron in solution was increased five to ten fold, but some copper was precipitated with the ferric and aluminum basic sulphate. However, on further agitation, this colloidal material approaches nearer to the composition of ferric and aluminum hydrates, and sulphuric acid is formed. The sulphuric acid formed redissolves the copper from the precipitate. Direct addition of sulphuric acid removes the copper immediately, if it is not desired to agitate the solution too long. The changes in these solutions were followed by the air electrode-calomel electrode, developed some time ago, which has been greatly simplified so that it can be used in dirty solutions and still indicate the points at which all the iron or aluminum or ferrous are precipitated from the pulp without the need of any chemical analysis. Numerous bimetallic electrodes were tested for their value in hydrolytic purification by the Bureau of Mines process. Some work remains to be done, but the process is believed to be adaptable to commercial use.

Oil Prospects In Southern Alberta[1]

By M. Y. WILLIAMS

Following the development of the Kevin-Sunburst oil field of Montana in 1922, active drilling operations were commenced just across the International boundary line in Alberta, about 19 miles from the proven territory. The border town of Coutts, Alberta, is near the scene of operations. Drilling commenced in the autumn of 1922, and by the spring of 1923 about one dozen wells were located, all but 3 being on the Quarantine Reserve, tp. 1, range 15, west of the 4th Meridian. By the commencement of summer, four wells were down from 1,700 to 2,850 feet, two of which reported favourable showings of oil. Four other wells were ready for drilling, and operations were planned by other companies.

Meanwhile the Kevin-Sunburst field developed until by the end of summer it contained 100 producing wells and comprised a territory about 11 miles east and west by 3 miles north and south. During the summer, however, crude oil dropped steadily to a low price of 50 cents a barrel. As a result, drilling operations slowed down, and the development anticipated on the Canadian side did not materialize. The Canadian companies engaged in actual drilling experienced many physical difficulties, and by autumn little had been added to the accomplishments of the early summer.

Geology. The oil of the Kevin-Sunburst field is obtained in the Kootenay (perhaps including the Dakota) sandstone and the underlying Ellis sandstone and shale of Jurassic age although oil is also found in the still lower Madison limestone. The wells average little more than 1,600 feet in depth, and start in the Colorado shale. As shown by D. B. Dowling in the Summary Report of the Geological Survey for 1922, Part B, the formations dip northward, the Kootenay in the vicinity of Coutts lying from 1,890 to 1,930 feet below the surface. The dip to the north between the Kevin-Sunburst field and the International boundary is about 1,150 feet. This drop in elevation makes the Canadian field less favourable for oil accumulation, but may not preclude the occurrence of commercial pools, in structures subsidiary to the main dome, or possibly separated from it by tight areas in the producing sands. The test wells in Alberta were located so as to explore promising terraces, and northward extensions of the Kevin-Sunburst structure. The locations were inspected by the writer and appeared to be marked terraces worthy of exploration

Nowhere in southern Alberta except in the vicinity of the Sweet Grass hills, referred to above, and in the foothills of the Rocky mountains, do the oil horizons rise as near the surface as they do in the Kevin-Sunburst dome. The Sweet Grass hills are intrusive plugs which have penetrated and domed up the Mesozoic formations, and their effect upon oil accumulation can only be told by drilling. When the writer left the field, late in September, two wells in Montana were approaching the oil horizons, one on the east and one on the west of East Butte. Both wells had struck flows of gas.

The structure of the foothills of the Rockies is complicated by intense folding and faulting, and has not as yet been closely studied by the writer.

Summary of Exploration

The results of drilling in the vicinity of Coutts may be summarized as follows, taking the wells in general order from west to east:—

Well drilled by Northwest Co., in Red Coulee, L. S. 6. Section 5, tp. 1, range 16, west of 4th meridian; Kootenay sandstone at 1,890 feet, oil reported at 2,505 in grey sandy shale, bottom of well in chert formation at about 2,670 feet.

Well drilled by Coutts Sweet Grass Oils, Ltd., on S. E. ¼, Sec. 1, tp. 1, range 15, West of 4th meridian. Kootenay sandstone at 1,900 feet, Ellis shale reported at 2,300 feet. Oil showings reported at 2,340 feet, 2,380 feet, 2,424 feet, 2,440 feet, 2,450 feet; and gas at 2,615 feet, and 2,850 feet; bottom of well at 2,852 feet. This well was lost because of a crooked hole and consequent loss of casing, etc.

Well drilled by Lethbridge Oils, Ltd., on S. E. ¼ Sec. 12, tp. 1, range 15, West 4th meridian. Kootenay sandstone at 1,950 feet, bottom of hole at 1,985 feet.

The logs of the foregoing wells were furnished by the companies concerned.

Well drilled by the Border Oil Co., with a diamond drill, on S. E. ¼ sec. 6, tp. 1, range 14, West of 4th meridian. Record made by the writer from examination of the drill cores: Surface deposits to 25 feet; Milk River sandstone to 203 feet; Colorado shale including sandstone beds and streaks to 1,860 feet; beds partly sand, partly shale, and thought to represent the Kootenay to 1,920 feet. Considerable oil made its way to the surface escaping against the feed water pressure, at a depth of 1,875 feet, and again at 1,920 feet. The well had reached 2,000 feet when last visited about the middle of September, the lowest 80 feet being shale.

A summary of the log of the diamond drill boring of the Troy-Sweet Grass Well No. 1, on N. E. ¼ S. W. ¼ Sec. 21, tp. 34, N., range 1 West. Toole Co. Montana is as follows: Elevation 3,543 feet; Colorado shale to 760 feet; Kootenay sandstone to 1,272 feet. Ellis (Jurassic) shale and limestone to 1,370 feet. Considerable oil in vugs and cracks in lime shale 1,365—1,370 feet. Sulphur water at 1,370 feet. Madison (lower Carboniferous) limestone to 2,153 feet. Oil showing through lower half of Madison in vertical fractures. Devonian shale and limestone to 2,486 feet. Oil showings at 2,209 feet, 2,338 feet, 2,475 feet. Probably Silurian (anhydrite) to 2,600. (Taken from graphic log by J. B. Gerlough).

Outlook. Several other deep wells have been drilled in the vicinity of the Sweet Grass and Kevin-Sunburst structures and other wells are exploring the areas between the oil fields and the gas fields to the northeast which are now proven as far as Etzikon Coulee, southeast of Foremost. The presence of large quantities of gas at the latter locality, in various horizons in the

Colorado shale, and of heavy oil in the Kootenay sandstone, is cause for hope that where suitable structure exists between the Alberta gas fields and the Montana oil fields, commercial pools of oil may be found.

The employment of competent geologists by companies exploring this region, is to be highly commended, as it is only on suitable structure that oil or gas accumulations are to be expected.

AN ELECTRON GUN*

Making Practical Use of the Ultimate Particles of Matter

Have you ever seen electrons pattering against a glass screen, like bullets from a machine gun on a distant target? Of course, one cannot see either the electrons or the bullets, but only their effect on the target. An electron is the smallest thing yet conceived as having existence as a separate body. Physicists estimate the diameter of an electron as a very small fraction of the wave length of light, itself about one fifty-thousandth of an inch. These tiny corpuscles of negative electricity and the relatively much larger positive ions are believed to be ultimate constituents of matter.

By processes now in daily use electrons can be separated from the atoms of some substances. Cathode rays, or streams of electrons, can thus be produced. Electrons have velocities which may be almost as great as 186,000 miles per second, the velocity of light. Notwithstanding inconceivable minuteness and great speed, electrons are in a measure controllable and are used in many ways every day. Apparatus for dealing practically with things so intangible to our unaided senses partakes of the fascination of magic.

Many devices have been made to employ the properties of electrons both in physical research and in the industries. One might mention the three-element vacuum tube whose use in radio has made it a household article. Another device is the low-voltage cathode ray oscillograph, devised about two years ago by Dr. J. B. Johnson in the Bell System Laboratories of the Western Electric Company.

For this particular oscillograph conceive a pear-shaped clear glass bulb with a long cylindrical neck and a carfully rounded big end nearly flat. The inside of the big end is made a fluorescent screen by coating it with a paste of suitable materials. Wherever and while electrons impinge on this screen, a brillant spot or line of greenish light appears.

At the base of the neck is the "electron gun"—not an old-fashioned blunderbuss, but a modern machine gun concentrating its fire within a small circle. With an electric current flowing, the electrons are shot off from a small cathode made of oxide-coated platinum ribbon in the form of a loop with its closed end bent into a ring at a right angle to the electron stream. To reduce damage to the filament from the blows of relatively heavy positive ions, this form permits them to pass the main portion of the cathode with relatively few "direct hits."

Immediately above the cathode is a metal shield with a tiny hole through its center. Directly above this hole is a thin platinum tube one millimeter in diameter and one centimeter long, which is the electrical anode and also the barrel of the "gun." It points towards the center of the target, or screen. The whole "gun," its electrical connections and its appurtenances are sealed into the tube airtight. An almost perfect vacuum is created inside the tube and then a very small quantity of argon gas is admitted. This gas helps greatly in concentrating the fire of electrons on a definite spot.

In the directing of its fire the electron gun differs from the ball and powder variety. The electron gun is not swung about, but its stream of projectiles is deflected by means of electric or magnetic forces. The deflectors consist each of two pairs of small parallel metal plates. One pair is at right angles to the other, while both pairs are parallel to the axis of the gun, which is the direction of the undeflected electron stream. The deflector is a short distance above the anode (the barrel of the gun). Therefore the stream of electrons passes between the plates of each pair.

The usefulness of this tube oscillograph comes from the fact that the stream of electrons forms a nearly weightless pointer whose movement will accurately follow the changing conditions in the circuit to which it is connected. No frequency that can be produced in in an electrical circuit is too high for this pointer to follow. Thus we can study the shapes of electrical waves from the lowest frequencies of power generators up through the speech range to the highest radio frequencies. This is very useful in generator design, in telephone engineering, in testing magnetic properties of materials, in radio, and in classroom demonstrations of all sorts of electrical phenomena.

* Research Narrative No. 67, Engineering Foundation, New York.

PREPARATION OF FERRIC SALTS

Investigative work on the preparation of ferric salts has been concluded at the Pacific Experiment Station of the United States Bureau of Mines, Berkeley, Calif. The object of this investigation was to prepare solutions of ferric salts suitable for the hydrometallurgy of complex ores, and by methods that would have promise of commercial success due to their simplicity and cheapness. Observations made at the Tucson station of the Bureau of Mines that ferrous sulphate solutions could be oxidized to ferric solutions by air containing a small amount of sulphur dioxide, with simultaneous formation of sulphuric acid, were taken as the basis of a long research on oxidation by air. In stronger solutions the first thing that happens is oxidation of ferrous to ferric sulphate from hydrolysing. Later, sulphuric acid begins to form and continues up to a 4 or 5 per cent solution. Acidity of the solutions tends to prevent these reactions taking place with any speed, particularly if all the iron is present at the beginning as ferrous sulphate. The optimum temperature for this reaction is at about 35 to 40° C., which is easily attained by using warm or hot burner, or roaster gases. The application of this process to the treatment of ores is being followed up by the Bureau of Mines at the Tucson station.

MANGANESE SHIPPED FROM BRAZIL

During August, 8,407 metric tons of manganese ore were shipped from Rio de Janeiro and 4,200 tons from Bahia. Of this tonnage the United States took 11,720 tons.—U. S. Commerce Reports.

THE MINING DISTRICTS

By THE JOURNAL'S CORRESPONDENTS

NORTHERN ONTARIO

Cobalt—During the month of October the Nipissing ined ore of an estimated net value of $175,800, and ipped bullion of an estimated net value of $64,537. While the output in ounces is approximately the same. hipments were smaller than usual. The low-grade ill treated 7,254 tons and the high-grade plant 177 ns, the refinery shipping 101,000 fine ounces of ullion. There were no unusual developments under-round, stoping operations continuing about the same. he company is proceeding with the development of he Powell and Waite claims in the Rouyn District, on hich it has taken an option.

The Colonial continues to meet with good results n its development of the lower diabase-Keewatin ontact at a depth of approximately 900 feet. The irst shipment of high-grade ore, consisting of 10 tons. as just been made, and stoping is resulting in a teady production. The shipments of mill rock to the Mining Corporations mill in Cobalt are being continued, nd it is understood that milling operations will hortly commence. The dispute as to the ownership of the big silver nugget recently found in the Gillies Limit appears to be the result of confusion as to the manner in which claim boundaries should be run. It is understood that some surveyors are of the opinion that with claims staked in that part of the limit thrown open in July 1920, the prospectors' lines govern, as in unsurveyed areas, while other surveyors believe that the claims must represent aliquot parts of a block. This naturally gives rise to a good deal of confusion, as it depends upon the particular surveyor doing the work which lines are to govern. It will, no doubt, be necessary to have a ruling from the Department of Mines on this point before the matter is cleared up.

Kirkland—The freight congestion in the Kirkland district is giving operators there a good deal of anxie ty and annoyance. The railway facilities will only permit the spotting of seven cars a day, while at present there are approximately 50 cars of freight waiting to be unloaded. This results in very serious delays and cars are sometimes held up for weeks. As soon as the branch railway is in operation into Kirkland this situation will, no doubt, be relieved; but in the meantime many delays are experienced. This is particularly the case with the Lake Shore, which expected to put its 300-ton mill into operation this fall. Due partly to delay on account of freight congestion and failure to deliver materials on time, it is probable that the enlarged mill will not be run ning until next spring. In view of this the manage ment has decided to proceed immediately with the continuation of the shaft to the 1,000-foot level. The main vein has recently been cut at 800 feet, where it shows values that compare very favorably with those on the upper levels. At 600 feet stopes have been opened for a length of almost 1900 feet, and there seems to be little question but that the Lake Shore has the richest ore of any gold mine in Canada. One stope, having a length of 350 feet, is stated to average over $50.00 a ton, while several other stopes also give high values.

In drifting toward the Lake Shore boundary, which is still several hundred feet away, the Wright-Hargreaves is also understood to be getting the richest ore in its history, and it is expected to result in higher mill heads. While the average grade treated by the Wright-Hargreaves is considerably lower than at some of the other properties, this company has been the highest dividend payer in the Kirkland district, but will, no doubt, be exceeded by the Lake Shore when the enlarged mill is in operation.

Better results are being encountered by the Kirkland Gold, some new ore having been found on the 400-foot level.

At the Tough-Oakes, developments continue to give good results, and it should not be long before that company's mill is once more put in commission.

The most important discovery in the Kirkland district in recent months has been made on the Lebel Oro, where some rich ore was encountered in the shaft.

Developments as a whole throughout the Kirkland district are exceedingly promising, and production next year should be double that of the present year.

A statement is being prepared by the officials of the Argonaut in connection with that property, which shows an encouraging state of affair and holds out a good deal of encouragement for the future. A considerable tonnage of good grade has been developer, and it is expected that early in the new year the tonnage will be raised to 200 tons a day. During the first few days of November the ore averaged $17.00 a ton, and costs have gradually been brought down until in October they were $6.30 a ton. One of the most important features in connection with the development of the property is the fact that the copper content of the ore decreases as depth is attained. The derable trouble, and when cyaniding was first started presence of copper in the ore has given rise to consi- the copper content was so high that it resulted in a very heavy consumption of cyanide and a poor extraction. For a time the cyanide end of the mill was cut out, and the gold was recovered by amalgamation and flotation, the flotation giving a copper concentrate carrying gold, which was shipped. Still later, amalgamation, flotation and cyaniding were tried, but it is now found that the copper content has diminished to such an extent that the flotation end of the mill can be cut out and a satisfactory recovery made by amalgamation and cyaniding.

During the first few months the mill was in operation the monthly recovery was comparatively low on account of the fact that a considerable portion of the tonnage was drawn from the old sand fore dumps. These have now been used up and all the ore is being taken from underground, with a consequent improvement in grade.

At the recent annual meeting of the Tech Hughes, held in Buffalo, one of the most important announce-

ments was to the effect that on the 10th level a length of 400 feet of ore had already been deve showed a grade comparable with that of any ore in the mine. When this level was first opened it was rumored that the ore was unpayable, so that this statement of the management clears the air. It was also stated that the good grade of ore now being obtained might be expected to continue to a depth of at least 2,000 feet. On the West workings of the 800-foot level ore averaging $40. a ton is being developed, with sections running as high as $100 a ton. The 400-foot level, which is being extended into the Orr property, is also developing high-grade ore. 15,000 tons of tailings, running between $4.00 and $5.00 a ton, have been impounded and will be treated later at an estimated cost of from $1.00 to $1.50 a ton, and these tailings have not been included in the estimate of ore reserves. It was announced that the bonded indebtedness, which in August amounted to $176,000, would be paid off on January 1st, the next interest date. At that time the company should have $200,000 cash surplus. The company has under consideration the sinking of a new central shaft and the building of a new mill. This will call for a considerable expenditure and the question of dividends will, no doubt, have to be deferred until the cash assets have been built up sufficiently to permit of this heavy expenditure.

An electrically driven mining plant has arrived at the Kirkland Townsite, which is under option to Anglo-Canadian Explorers, Limited. This will be set up and shaft sinking started. Several diamond-drill holes have been put down and two sections, carrying encouraging values, have been located.

An unfortunate situation has arisen in connection with the Murray-Mogridge property, on which it was recently stated that an option had been taken by the Tonopah Mining Company. It now appears that some time ago an option was given to English interests and that the subsequent option was given to the Tonopah Mining Company without their knowledge. The property is understood to have a good deal of merit, and it is unfortunate that such a condition should have arisen.

BRITISH COLUMBIA

Coal Mines Regulation Act

It is announced that the "Coal Mines Regulation Act" of British Columbia is to be amended at the Session of the Provincial Legislature now in progress to provide that all cases of ignition of gas or dust underground, all cases of fire underground, all cases of breakage of ropes, chains, or other gear by which men are lowered or raised, all cases of overwinding cages, all cases of inrush of water from old workings and any other dangerous occurrence shall be reported to the Inspector of Mines. At present this is not obligatory unless someone is injured, fatally or otherwise, as a result. Penalties, also, are to be substantially stiffened. If a false statement is made in any report or entry required under the Act the penalty, on conviction, is to be imprisonment for a term not exceeding two years. Anyone found guilty of an infraction against the Act shall, if he be owner, agent, or manager, bring a fine not exceeding $1,000 and, if he be any other person, a fine not exceeding $100. As the Act now reads the respective maximum fines are $100 and $10. It also set out that "if the inspector has given notice of an such offence, then in the case of an owner, agent manager "there will be a further penalty" not exceeding $1,000 and not less than $100 for every da after such notice that the offence continues to committed and in the case of other persons to a fu ther penalty not exceeding $50 for every day afte such notice that the offence continues to be com mitted." These more stringent punishments, no doub are the result of the continuance of both major an minor offences against the Act notwithstanding tha wherever evidence is secured, prosecution has bee instituted.

Sales Tax on Fuel Oil

Those associated with the coal mining industry i British Columbia have been interested in the recen reports of the efforts being made by the Hon. Wm Sloan, Minister of Mines, to induce the Provincial Gov ernment to place a sales tax on fuel oil used in Bri ish Columbia. The minister has taken the position fo years that the production of local coal and the domesti market upon which it chiefly depends are being seriously affected by the growing importations of foreign fuel oil. He has pointed to the decreasing annual output of the coal mines of the Province since the year 1910 and the increasing output of oil on the Pacific Coast in substantiation of his contention. He has pointed to the conversion of locomotives to fuel oil burners, to the installation of fuel oil consuming heating plants in business blocks, to the use of the same fuel to a larger extent than ever in the homes of the people, and has asserted that, if the basic coal industry of the Province is to be maintained, it must have some assistance in its fight against the further constriction of its market. While no official intimation is available it is understood that Mr. Sloan's efforts have been successful and that the Government will give the Legislative Assembly an opportunity of passing on the proposal of the imposition of a small sales tax on imported fuel oil.

Canadian Western Fuel Co., Ltd.

Formal notice has been given of a meeting of the Canadian Western Fuel Co. Ltd. to be held at the office of the Western Fuel Corporation of Canada Ltd. at the City of Nanaimo on Tuesday the 11th December next for the purpose of "having an account laid before them by the liquidator — showing the manner in which the winding up of the said Company has been conducted and the property of the Company disposed of and of hearing any explanation that may be given by the Company."

Canadian Collieries Limited

Lieut.-Col. Charles Villiers has been appointed General Manager of the Canadian Collieries (D) Ltd to succeed the late J. M. Savage. Mr. Thos. Graham who has been performing the duties of General Manager temporarily, will continue with the Company as General Superintendent in charge of operations. Col. Villiers formerly was assistant manager of the Johannesburg Consolidated Investment Co. He was for a time General Manager of the African and European Investment Co. which controls several coal mines of the Transvaal. He also was with the Transvaal Chamber of Mines

Victoria and Vancouver District

Dale L. Pitt, manager of the Premier Mine, Salmon iver, Portland Canal, and Mrs. Pitt are visiting Vic-oria and Vancouver. It is reported by Mr. Pitt that he heavy rains of the early part of November did uch damage to the roads leading from tidewater to he mines of the district. Washouts from the side-ills blocked the road and washed out, in some cases, ridges and culverts. Traffic, however, was only held p for two days, large gangs being put to work on epairs. The new Bear River bridge had a narrow scape some of the false work and piles being carried way. Fortunately the superstructure was not in lace or the effects of the storm would have been erious. Five hundred tons of ore a day are being roduced at the Premier Mine, shipments to the smelter mounting to 300 tons and the concentrator turning ut 200 tons. — The Idaho Group of Mineral claims, tuated on the north fork of the Marmot River, six iles from tidewater and at an elevation of 4,800 feet, highly spoken of as a result of recent development. t is said that 15 tons of high grade ore running over 300 a ton in gold, silver, and lead have been sacked or shipment. In some 375 feet of underground work series of high grade veins are said to have been pened up, one vein having been driven on for a istance of 28 feet. The property is being syndicated ith a view to raising capital for further development. . B. Fugier, president of the Gloria Mining Co., be-eves that this property, located just below the mouth f the Marmot River, will prove attractive from a illing standpoint. The mineralization is extensive nd development is to proceed through the winter.

Tragedy at Princess Royal Island

A double tragedy occurred recently at the mine of he Belmont Surf Inlet Mining Co., Princess Royal sland. Kenneth Brown, a 19 year old youth, em-loyed as sampling assistant to the mine engineer, ell into a tool raise and was instantly killed. Gus aurin, a miner, 25 years, fell a distance of 150 feet nto a stope and died of his injuries some hours later.

Fiddler Creek

J. F. Duthie, who came into prominence among western mine operators through his successful devel-opment of the Henderson Group near Smithers, B.C., s reported to have acquired what is known as the Fiddler Creek Mining Property, 130 miles east of Prince Rupert. It is contemplated spending $150,000 n development and Mr. Duthie looks forward to shipping ore in a few weeks. Surface plant proposed includes a tramway, power plant and mill.

Steel Group

The shipment of several carloads of ore to the Trail Smelter in recent months from the Steele Group of Mineral Claims, owned by the Alice Arm Holdings Co., Ltd., of Vancouver, B.C., has directed attention to this property. It is situated near the Columbia River in East Kootenay and is reached by wagon road from Brisco on the Kootenay Central Ry. The ore is brought down to the bench below by a light aerial tram about 1,200 feet long, from the lower terminal of which it is hauled over the rawhide trail for a distance of about 2 miles to the road. The vein occupied a fault fissure apparently conforming in strike and dip to that of the formation. It can be traced easily for a considerable distance and is thought to be a continuation of the "Lead Queen" vein. Carrying on previous development the present Company has uncovered the vein for a distance of about 65 feet along the strike by a deep open cut, showing an average width of 2 feet of ore consisting of steel grained galena associated with disseminated iron pyrites in highly siliceous gangue. A sample showed a trace of gold, silver 18.1 oz., lead 23.3 per cent and zinc 2.4 per cent. It is said that the Company mined 700 tons of ore between January and March of the present year and that the returns were 5,126 ounces silver and 139,543 pounds lead. The installation of a mill is contemplated.

Rossland Mines

Work on the ore of the Rossland Mines started recently at the Trail concentrator of the Consolidated Mining and Smelting Co. of Canada. The concentrates will be stored until sufficient has been accumulated for a run of the copper furnace at the smelter. Until the necessary tonnage is available the copper rod mill at Trail cannot be operated. If the Copper Mountain Mine were to resume work the copper production would be so increased that it would be possible to open the rod mill of Trail and of that there appears to be little present prospect.

Cork Province Mine

The announcement is made that the Cork Province Mine was operated during the month of September at a profit of $5,000. Lack of water is said to be hampering the management, the power available being inadequate. It is proposed that steps be taken to provide the equipment essential to put the company out of reach of such inconveniences in the future.

"Molly Hughes"

The "Molly Hughes Mining Co. Ltd." was incorporated in British Columbia on the 27th October last, its head office being New Denver, B.C., and its capitalization $500,000. The "Jubilee Mining Co. Ltd." is another new incorporation. It made its bow on the 6th November last with a capitalization of $25,000 and head-quarters at Greenwood, B.C.

Chief Engineer Dead

Ethelbert G. Woodford, 73 years of age, and a mining engineer of wide repute, died in Seattle Wn. on the 9th of November. At one time he was chief engineer for one of the large diamond mine corporations of Kimberley, South Africa, and later was engaged in mining engineering work in Alaska.

Trail Smelter

Ore receipts at the Trail Smelter of the Consolidated Mining & Smelting Co., of Canada totalled 4,133 tons. The shipments in detail follow:

Mine	Tonnage
Bounty Frac., Beaverdell	2
Company Mines	3,547
Cork Province, Zwicky	48
Lone Pine, Republic Wn.	57
Ottawa, Slocan, B.C.	19
[illegible]	[illegible]
Quilp, Republic Wn	141
Silversmith, Sandon	91
Standard, Silverton	169
Total	4,133

NOVA SCOTIA

Nova Scotia

The question whether Alberta coal is carried to the far east of Ontario or not it is becoming more evident every day that coke from Nova Scotia will ere long come into close competition with American anthracite and no doubt wrest a fair share of the market from American coal companies. To begin with the market for coke lies in the territory now supplied with Nova Scotia bituminous and a beginning here will lead on to further extension. The collieries of Nova Scotia produce good coking coal for domestic use. They are well developed and capable of filling large orders within a very short time. The ovens are all ready built and there is enough expert information on domestic coke to enable the B.E.S. Co. to go into this work without fear of falling down or even of delay in filling orders. The public have begun to recognize that more can be done in solving the coal problem of Canada by assisting Nova Scotia coal than coal from the West. Distance does not play such a large part in marketing Nova Scotia Coke and when the time arrives that it will become a factor which handicaps, there will be sufficient data gathered to guide in reaching out for further markets if the collieries can supply them. Alberta coal has had its trial, Nova Scotia awaits with calm complacency its turn and if the powers that be are favorable, then with a fair field we ought to win.

Phalen Seam

A bore hole was put down on the Phalenseam at Lingan to test the measures before sinking begins. This seam was struck at a depth of 428 feet. On the way down the hole pierced five different seams, three of these were less than 3 feet thick one was four and the other 5 feet thick. The Lingan seam at the point where entered by the borehole showed 7 feet of clean coal of fine quality. This conclusively proves that the stone band which separates the coal of the rise workings of this seam thins out to nothing to the dip leaving the coal without even a trace of splint or refuse material where the coal comes together. This is exactly the conditions on the other side of Lingan Harbor and proves beyond all question that the Lingan colliery was on the Phalen seam. The new colliery about to be opened up on this seam will be close to the shore line but will have at least over 300 ft. cover where it enters the under-sea areas. The coal gradually dips to the ocean and while the workings are being extended in that direction there may be sufficient land coal to provide a fair output.

BOOK REVIEWS

THE METALLURGY OF IRON AND STEEL, by Bradley Stoughton—third edition, 1923—McGraw-Hill Book Company, 370 Seventh Ave., New York. —520 pages—price $4.00.

During a lifetime devoted principally to the iron and steel industry of his native country, Dr. Stoughton has become its public representative. His book, published first in 1908 and revised in 1911, is a standard text-book on this continent, and has been used widely beyond school and college walls. There is, therefore, a host of old friends who will welcome this 1923 edition of the work, which has been largely re-written, as necessitated by the changes in iron and steel metallurgy during the last twel years.

In his preface to this new edition, Dr. Stoughton d lineates briefly and clearly the trend of the metallurgic development of these years. The growing demand f high-grade iron and steel products, culminating in th specifications for munitions, has stimulated research on scale not dreamed of a comparatively few years ago. Th research has brought improvements and changes in pra tice that in some cases are revolutionary. Neverthele Dr. Stoughton points out a great deal of fundamental re search still is required, if American ferrous metallurgist are to equal their European confrères in providing th great, basic ideas upon which most progress is built. Thi and much more, is reflected in Dr. Stoughton's new boo —for the extensive revision makes it virtually that. W are loath to replace our old friend the 1911 edition, o our shelves, by this newcomer; but we, too, must try t keep up to the times.

GEOLOGIC STRUCTURES, by Bailey Willis—Mc Graw-Hill Book Company, 370 Seventh Ave., Ne York.—295 pages.

An adequate understanding of nature's processes is th foundation upon which is built a large part of our ma terial prosperity. In no sphere of practical endeavou is this more evident than in the work of the mining engi eer and mining geologist. The secret of success in hi case, probably more than in any other, is a correct inter pretation of evidence provided in nature. Dr. Willi book is a detailed study of a phase of geology that is in timately connected with problems the miner must solv He examines the nature of strata, joints, faults, folds an veins and the processes that produce them. Mineral de posits result, to a notable extent, from movements in th solid rock, and to these he devotes particular attentio We commend the book to those who wish to extend or t consolidate their knowledge of this phase of nature's ac tivities.

UNEMPLOYMENT IN GERMAN INDUSTRY

Figures obtained from a reliable source connecte with the Government reflect the seriousness of the em ployment situation in Germany. It is estimated tha on October 16 there were 1,500,000 workers totally un employed in the unoccupied sections of the country In addition to these there were between 4,000,000 an 5,000,000 workers on part time, including 2,000,00 working only half time or less.

The unemployment doles paid by the Governmen and the individual municipalities are totally inadequat to cover the cost of necessities. The maximum allow ance to a married man with wife and two children for the week, ending October 16, was 1,800,000,00 marks a week, whereas a loaf of bread weighing 1,20 grams, cost 480,000,000 marks, a pound of potatoes 50 000,000, and a pound of margarine 900,000,000 at tha time. The minimum allowance for a married man wa 1,400,000,000 marks, for an unmarried man 810,000,000 and for an unmarried woman 600,000,000. It is es timated that the dole received by a worker cover about one-third of the wages he would have received working. For example, a married man with wife an two children received in Berlin for a week of half-tim work 3,100,000,000 marks in wages and a dole of 1,500 000,000 marks.—**Commerce Reports.**

TIN EXPORTED FROM STRAITS SETTLEMENTS DURING AUGUST

Total exports of refined tin from the Straits Settlements amounted to 4,990 long tons in August, compared with 4,865 tons in July. Of the August shipments, the United States took 85 per cent, the United Kingdom 7.3 per cent ,and continental Europe the balance. The highest price for the month of August was $98.25 per picul, against $95.125 for July; the lowest, $92, against $88.50; and the average, $95.04, against $91.46.—U. S. Commerce Reports.

TIN SHIPPED FROM FEDERATED MALAY STATES DURING JULY

The exports of tin ore from the Federated Malay States (72 per cent) during July amounted to 47,009 piculs 30 catties, and aggregated 299,396 piculs 73 catties for the first seven months of 1923, compared with 287,211 piculs 69 catties for the same period in 1922. Tin exports for the month were 7,915 piculs 43 catties, making the total of 55,792 piculs 46 catties for the period January to July inclusive, compared with 57,992 piculs 40 catties for the same months in 1922.—U. S. Commerce Reports.

OUTPUT OF BALDWIN MINES IN BRITISH INDIA REPORTED

The output of the Baldwin Mines in British India during August amounted to 20,161 tons of ore. The refinery produced 3,810 tons of refined lead and 434,680 ounces of refined silver, and the experimental zinc plant, 940 tons of zinc concentrate assaying 9.9 ounces silver, 6 per cent lead, and 48.6 per cent zinc. In addition to this 125 tons of copper matte were produced from accumulated smelter by-products.—U. S. Commerce Reports.

BRITISH EMPIRE EXHIBITION

Viscount Long of Wraxall has accepted the Presidency of the forthcoming Empire Mining and Metallurgical Congress to be held at the British Empire Exhibition on June 3rd to 6th (inclusive) 1924, of which The Prince of Wales is Honorary President. The following official personages have accepted invitations to become Honorary Vice-Presidents of the Congress: The Secretary of State for the Colonies; The Secretary of State for India; The Secretary for Mines; The Prime Ministers of Canada, Australia, New Zealand and Newfoundland; The High Commissioners of the Dominions and British India; and The Lord Mayor of London. The Presidents of the seven Convening Bodies will act as Vice-Presidents and will preside over the Sections with which they are concerned.

BRITISH EXPORTS

Exports of iron and steel products from the United Kingdom for October were 388,599 long tons, the largest month but one (the May total reached 424,509 tons) and 10 per cent greater than the monthly average of 353,500 tons for the nine months of 1923. The products showing a marked increase over previous months were tin plate, with 51,400 tons; galvanized sheets, with 57,800 tons; and sheets and plates, with 50,500 tons.

"When You Are Hundreds of Miles from a Cow—"

ALL you need is Trumilk or Milkstock and you will never lack an ample supply of fresh country milk.

Trumilk is powdered full cream milk packed in 45 lb and 90 lb. drums. It can be used in any way in which pure fresh liquid milk can be used.

Milkstock is powdered skimmed milk in 50 lb and 100 lb. drums and is suitable for all cooking purposes. These two invaluable products are easy to ship, easy to keep and to convert them back to liquid milk again, all you need is water. Order some for the Camp *today*.

INDEX TO MINE AND MILL SUPPLIES

Addresses of advertisers whose names appear in the following classified index, may be found upon reference to their advertisements. An alphabetical index to advertisers will be found on the page facing the inside back cover. The following regulations apply to all advertisers: — One-eighth page, every issue, three headings; one-quarter page, every issue, six headings; one-half page, every issue, twelve headings; full page, every issue, twenty-four headings. Buyers who are unable to find in the classification here given such machinery or supplies as they desire are invited to write Service Dept., Canadian Mining Journal, Gardenvale, Que., who can, in all probability, refer them to proper sources.

JET CONDENSORS AND CRANE PIPING IN A LARGE POWER PLANT

REDUCING YOUR CONSTRUCTION COSTS

In the construction of piping systems much time and money can be saved by the use of materials accurately made, eliminating costly hand-fitting at the time of erection. Experienced workmen, using the most modern machinery and methods, produce Crane valves, fittings, pipe bends and allied specialties to precise measurements, to make them easy to assemble. Crane equipment meets every piping need, including the severe requirements imposed by high pressures and excessive temperatures.

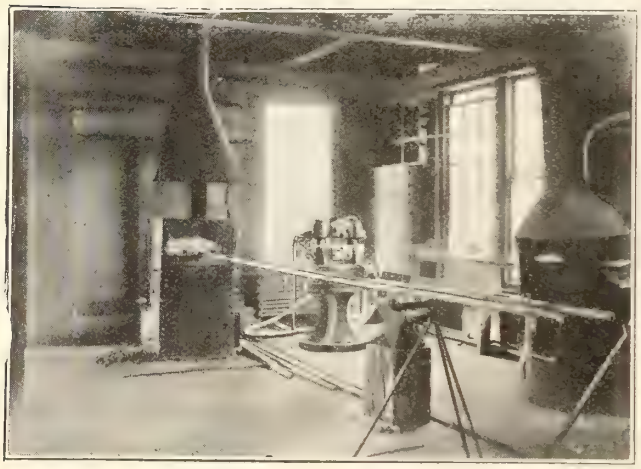
13 "Leyner" Sharpeners under one roof at The Robinson Deep Gold Mines



Leyner sharpener at a Black Lake Asbestos and Chrome Property

Underground sharpening shops cut steel handling and sharpening costs

One of two "Leyner" Sharpeners at the Lake Shore Mines, Kirkland Lake, Ont.

"Unsurpassed for

The efficiency of the entire rock-drilling plant is dependent upon the condition of the drill steel bit.

No matter how efficient the compressing plant, the mining method and the rock drills, or how careful the operator, if the bit is dull or of incorrect shape, the rock is not cut. Expensive energy is wasted and money and time are lost.

Hand sharpening is, at best, expensive and unsatisfactory, because the accuracy and quality required in a good bit cannot be attained on a commercial scale by using this method.

This is realized by the important mining and contracting companies who have installed "Leyner" Sharpeners to take care of their work. Every installation has confirmed the correctness of the choice.

Bulletin K-201-B, just off the press, describes "Leyner" Sharpeners in detail. Write for a copy.

Ontario's Minerals

PROVINCE OF ONTARIO

Hon. CHARLES. McCREA, Minister. DEPARTMENT OF MINES *Thos. W. Gibson*

Mineral Areas

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favourable for the occurrence of minerals 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver veins of Cobalt, Gowganda and South Lorrain occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

Economic Minerals

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario: — actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluorspar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, Portland cement, brick and tile, meet every demand.

Mineral Production

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1922 to be worth $62,202,169, of which the metallic production was $38,190,711.

The following figures show the growth of Ontario's mineral industry by five-year periods since 1891 when a Bureau of Mines was first established.

Year.	Value.	Year.	Value.
1891	$4,705,672	1911	$41,976,797
1896	5,235,003	1916	65,303,822
1901	11,831,086	1918 (Maximum war output)	80,308,972
1906	22,388,383	1921	48,128,387

Dividends.

Dividends and bonuses paid to the end of 1922 amounted to $28,096,699 for gold mining companies, and $86,238,185 for silver mining companies or a total of $114,334,884.

Mining Regulations

A miner's license costs $5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of $2.50 or $3.00 per acre, depending on location in unsurveyed or surveyed territory.

Assay Office

The Provincial Assays Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario

Link-Belt Silent Chain Successfully Used on Thomas Hoist Since 1904

THE Thomas Elevator Co. of Chicago, are using (as standard equipment) the Link-Belt Silent Chain Drives on their Friction Drum Electric Hoists.

Here is another instance where the advantages of Link-Belt Silent Chain in the efficient transmission of power, have merited adoption by one of the country's foremost builders of elevators and hoisting machines.

The illustration shows Link-Belt Silent Chain Drive on the type "W" Frame Thomas Three-Drum Electric Hoist, driven by a 75 H. P. variable speed motor, with Thomas automatic irreversible motor brake.

Use the Link-Belt Silent Chain Drive on ***your*** equipment. It is flexible as a belt—positive as a gear—more efficient than either.

Send for Link-Belt Data Book No. 125. Return the Coupon.

Assisting in the Development of the Mining Industry

It is essential that the peculiar banking needs of those engaged in the exploitation of Canada's natural resources be met with special facilities.

The Imperial Bank, ever a constructive element in the progress of Canada, long since realized the need for interested financial service to enable the proper development of the mining industry.

By opening branches throughout the mining districts and continually adding to them, as necessitated by expansion, this Bank has materially assisted in the development of the industry throughout Canada.

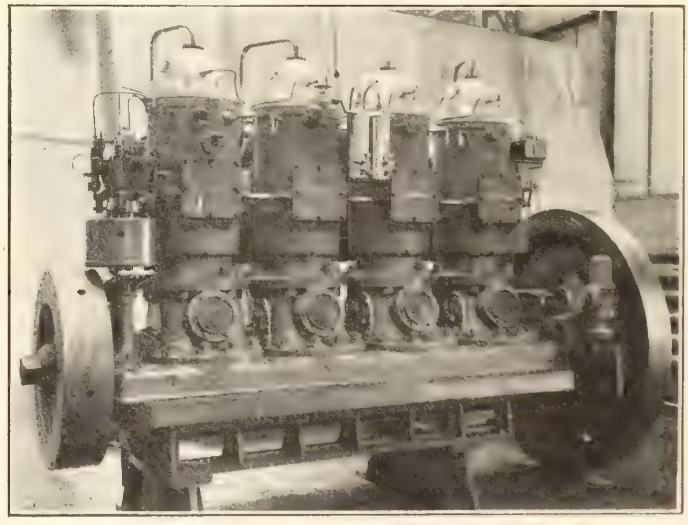
Those whose business is mining will find our facilities adequate and our knowledge of conditions valuable.

IMPERIAL BANK OF CANADA

Peleg Howland, President.

A. E. Phipps, General Manager

Holland has over 10,000 Semi-Diesel Engines in Service



KROMHOUT Semi-Diesel Engine 200 B.H.P.

For small powers, say up to 500 B.H.P. we recommend the SEMI-DIESEL in preference to the DIESEL engine :

BECAUSE :

First cost is less—therefore Capital and interest charges less.

It has fewer working parts, operates at a lower Pressure.—therefore depreciation and cost of upkeep less.

Is lighter and less bulky—therefore easier to transport and install.

Is of more simple design—therefore obviates the services of a skilled engineer.

Particularly suitable for standby or Reserve Power.

THE CRUDE OIL ENGINE CO. OF CANADA

BEGINNER'S LUCK

Here is the story of a greenhorn's luck — or good judgment.

Mr. F. S. Arntfield is a business man of Toronto. Last winter he was caught in the excitement of the Quebec gold boom and bought a claim. Last summer, after the flies had gone, he came north, hired a couple of bushmen and started out to find and examine his embryo gold mine.

The terminus of the canoe route was Renaud Lake, near the Lake Fortune property. From there it was a weary tramp to the claim in the northern part of Boischatel township; and it was not helpful to find that it was the veriest "wild-cat" — mostly swamp, and the rest hopeless for gold.

Instead of returning to Toronto damning the country, the prospectors and all else, as most men do when "stung", Mr. Arntfield determined to do some first-hand prospecting. He visited the Lake Fortune camps and there learned what gold ore and a schisted zone look like. A few days afterward, wandering through the woods within half a mile of his camp, he found schist which proved, first on panning and then on assay, to be gold ore. Stripping corroborated the evidence of the outcrop, and a further search revealed two additional shear zones close by, both gold-bearing as well. Mr. Arntfield then staked his first claim, the date on his discovery post being September 10th, 1923.

Acting on the advice of his new-found friends of the Lake Fortune, Mr. Arntfield kept his find quiet, and by staking and purchase soon had increased his original 180 acres to the respectable total of 2,000 acres, covering two miles along the strike of the shear zone. Then he talked — just a little — and now there is a rush to Boischatel township, and it is staked solid. The Arntfield property is looked upon as "a winner." Thus has the tyro outdone the professional prospector. Some will say it is luck pure and simple; but we know that, mixed with the luck, there is a fund of common sense, an unusual amount of dogged pertinacity, and that insatiable curiosity and constant high hope without which the prospector cannot successfully ply his trade. A good prospector was spoiled when Mr. Arntfield went into business; but he has done his bit for the country's mineral industry within these few weeks, after a well-filled life in another sphere of activity.

There must be many natural-born prospectors wasting their talent in the cities. It would be a good thing for themselves, as it might be also for the mining industry, if these took their vacation (after fly time!) in the north woods instead of Muskoka or Atlantic City. Prospecting in Canada is one of the finest games on earth. There are too few playing the game, and the field is open to all comers.

RESEARCHES IN CRUSHING

Crushing is one of the essential parts of ore-dressing in almost all mining and metallurgical plants, and where a finely divided product is required, it is one of the chief items of expense. It is, therefore, rather astonishing that the development of crushing methods has been left mainly to chance and to the fortuitous inspirations of inventors. The laws of crushing, as so far expounded, are principally of two kinds; either they are formulae developed by mathematical reasoning, and then grafted upon the various crushing operations; or they are empirical statements based, usually upon insufficient and inconclusive experimental data.

It is a pleasure, therefore, to find that Canada is taking a lead in fundamental research on crushing. It has required, as usual, the perception of outsiders to bring us to an adequate realization of what is going on within our own borders. We refer to the work of Professor H. E. T. Haultain and his associates in the University of Toronto. In order to stimulate similar activity in the United States, the American Institute of Mining and Metallurgical Engineers has induced Professor Haultain to undertake a lecture tour, with a view especially to showing his latest series of motion pictures illustrating the action of balls in tube mills. This tour was concluded at the Massachusets Institute of Technology ten days ago, and was a pronounced success.

It is to the good cause of research along these lines that the Hollinger Mines has contributed the substan[illegible] To discover the facts that govern the various processes of crushing, and then to devise mechanisms that will work in accordance with these facts, is a task of no mean proportions. It will require years of patient [illegible] principles, their worth is not so obvious to the out[illegible] public authorities can give it, and its progress will be

speeded up very materially by the added assistance of private corporations.

It is seldom that sound scientific method and a spectacular appearance are found in conjunction, as is the case with Professor Haultain's motion pictures. It is fortunate that this is so, for it will attract widespread attention to the whole problem of crushing with a rapidity that would not otherwise be possible, and will stimulate within a twelvemonth interest that it would take years to induce by more prosaic means.

LOW SALARIES A MENACE TO DEPARTMENT OF MINES

The Ontario Department of Mines' geological staff will soon be at half strength. In September last Mr. Cyril W. Knight resigned to join the staff of the Nipissing Mining Company. Now it is announced that on April 1st next Mr. Percy E. Hopkins will resign to join the Mond Nickel Company. The Company is wise to secure the services of Mr. Hopkins, as he is a born prospector as well as a highly trained pre-Cambrian geologist; but the Department of Mines will find it impossible immediately to replace his services with those of another equally proficient, and it will pay dearly for the loss incurred while a successor is learning his work.

The provincial geologist, Dr. Miller, has had much to do with directing the destinies of Ontario's mineral industry for the past twenty years. Mr. Knight joined him when Cobalt was a prospect, and became assistant provincial geologist. Mr. Burrows joined the field staff in 1907, and has paid particular attention to the Porcupine gold area from the time of its discovery. A year or two later Mr. Hopkins made a fourth in the quartet that have made the geological service of the Ontario government famous, not only throughout Canada, but far beyond. Now Dr. Miller and Mr. Burrows are left to carry on the work and to train the younger men who now must be added to fill the Department's complement.

Both Mr. Knight and Mr. Hopkins have been happy in their work in the public service. It is a fine work, with numerous attractions that commercial employment cannot offer. The reason they have left is, of course, because they can get more pay, probably double, in private employ. At one time during the period of high prices juniors on the staff in Toronto were not being paid a living wage; then a small increase was made to bring salaries over the border line. It is with reluctance that both these geologists have left the public service; but the possibility of earning enough in private employ to provide not only a good living but a competency for the future has proved to be an irresistible attraction.

There are some who say that no government can compete with a private employer for the services of a skilled technologist. We do not believe this to be the case. There can be a considerable discrepancy between the rates of pay in public and private service and, due to its inherent attractions for some men, the public service will hold them. It is only when the difference in the rates of pay is extreme that there will be a wholesale exodus from the public service.

From our present knowledge of the case, we judge that the salaries paid to geologists in the Ontario Department of Mines are inordinately low. It may be that the salaries of geologists cannot be raised unless those of some other departmental officials are raised also. In that case these latter should be adjusted as well. If two more geologists should resign from the staff, there will be no geological force at all. Both have been much sought after at times by private interests, and it is quite possible that the exodus will become complete.

These two resignations have shown that, under the existing policy of the Ontario Department of Mines there is no sufficient assurance that an effective geological staff will be kept together. In the final analysis, it is the Minister of Mines who is responsible for the Department's policy. We hold it to be the urgent duty of Mr. McCrea to investigate this question, and to assure the mining public to whom he is responsible either that it is impossible to raise the salaries of the Department's geologists, or that he has taken steps to see that this will be done.

THE GOLD BELT

In the December issue of the Bulletin of the Institute is printed the unusually thoughtful and able address delivered by Mr. C. M. Campbell at the Trail meeting in October. The admirable features of this address have been referred to before in these columns, as well as those points on which we do not see eye to eye with Mr. Campbell. The future of our mineral industry is a topic of such importance that it will bear discussion at any time. We welcome, therefore, a further statement from Dr. Corless, which appears on another page. In this he sets forth once more a very important point to which Mr. Campbell gives scant attention — the problem of finding the mineral deposits that will make the new mines on which not only the progress but the very existence of the industry depends.

If Mr. Campbell had been with us in Kenyn and Boisehatel townships last week, and had seen what we saw there, we are inclined to believe he would not have discounted the future so severely as has been his wont. True, there is nothing as yet disclosed there that can be added to a national inventory of ore reserves; but the outcrops so far located are such strong evidence of what will be disclosed by underground exploration that one cannot fail to believe that at

least one or two mines will be developed beneath them.

As noted in the description on another page, three small sections in these two townships have been subjected to intensive prospecting during the past season. On the Lake Fortune and adjoining claims this work has been confined to less than 100 acres. On the Noranda groups in Rouyn township a somewhat larger area has been examined. Round Pelletier Lake a dozen patches of land of a few acres each have received attention. In half-a-dozen scattered localities throughout the two townships the ground has been run over by prospectors and a small amount of trenching done. The area of the two townships is 200 square miles, or 128,000 acres. A large part of this is good prospecting ground, on whose outcrops a prospector has never yet set eye. Since the three localities already examined have contained such promising deposits, it seems more than likely that further search in unprospected ground between will disclose more of them.

The two townships of Boischatel and Rouyn cover twenty miles of a gold-bearing belt 100 miles in length. Except for some restricted localities where navigable waterways cross it, no systematic search has been conducted along the remaining 80 miles of this belt. Geologists have determined that, with some possible exceptions towards the eastern end, the whole belt is favourable to the occurrence of gold deposits. If the section so far examined is a fair sample, the future of the 100-mile belt is bright.

So far there has not been a single payable deposit proved on this gold belt. Yet experienced mining men are paying out thousands of dollars a week in the aggregate in development work, firm in the conviction that they will gain a good return. They are spending their money cautiously, as befits good business men; but the outcrops they have stripped and sampled simply compel expenditure on a large scale.

It is the point of view that directs these pioneers in a new mining field that Dr. Corless has exemplified and has defended so well. It is an entirely different point of view, namely that of the plunger or the wild enthusiast, that Mr. Campbell condemns with such fervent enthusiasm. "Inconceivable wealth" is neither here nor there; it is merely a phrase that will serve a useful turn in good hands, or can be much abused in the months of ignorant or scheming persons.

We shall not know before next spring whether or not the present prospects will make mines. It will take years to explore the whole gold belt. Meantime, though two railways are pointed towards the prospective mines, we may rest assured they will not be extended until there is full warrant. And, if the wild-catter can be kept out of the field, we may likewise depend upon the wise expenditure of the money required to find out what the field contains.

It may well happen that there will be won from Quebec's gold belt the wealth of the Rand; or the present evidence may be misleading, and we may have there only a few small gold mines. Whatever the result in this case, those in the mining industry charged with the responsibility of exploration must press forward, not only with the hope but with full assurance that their efforts will be rewarded. It is to aid in the search that Dr. Corless has painted his picture of the future. But at all times we must observe the precautions that guide mining as well as all other enterprises at their best. To emphasize these precautions Mr. Campbell has accepted as his task.

AWARD TO THE LATE J. D. MACKENZIE

It is with particular pleasure that we note the award of the Leonard Gold Medal by the Engineering Institute of Canada in recognition of the outstanding merit of the paper on "The Coal Measures of Cumberland and Vicinity, Vancouver Island," that was presented by the late J. D. MacKenzie at the Annual Meeting of the British Columbia Division of the Canadian Institute of Mining and Metallurgy in February of last year.

J. D. MacKenzie was a man who won the hearts of all who knew him and his work was inspired by genius of enduring value. To pay tribute to such a man is a privilege and we, among his many friends, tender to Mrs. MacKenzie the assurance of the personal gratification the bestowal of this honour has for us.

The paper is published in the Transactions of the Canadian Institute of Mining and Metallurgy for the year 1922, and has already been accepted as the standard work upon the "Island" coalfields.

NEIL R. MACDONALD

The Canadian mining fraternity has lost a picturesque figure in Neil R. MacDonald, who died in Montreal on November 20th of pleuro-pneumonia after a few days of illness. He was little past the prime of life, and had many years before him but for this sudden seizure. It is almost anomalous that he should have passed out in the Canadian metropolis rather than in the camp, military and mining, where he spent so much of his life.

The "Foghorn" is no more. He will be missed at many a gathering where his marvellous vocal power and his equally wonderful gift of expression entertained the whole assemblage. He was known from side to side and from end to end of this continent, and during his term of enlistment, first as a private in the infantry, and then as an officer with the tunnellers, his fame spread abroad in the old land.

"Foghorn" was a Glengarian, and trained for the priesthood at Ottawa College. His impulse for adventure overcame the influence of his training, however, and the woods and the camps soon claimed him for their own. He was always equally at home on the trail and in a drawing-room — though one can hardly say he acceded to all the conventionalities of the latter. His hearty, bluff manners were an attraction to all and compelled attention wherever he went. The "fog-horn" will amuse and entertain his fellows no more, but his memory will long remain with us.

A British Empire Mining Council

Such is the project that the eminent English mining engineer, Mr. Hugh F. Marriott, has been advocating in his original and very practical way, by a voyage around the world, keeping to the British possessions and speaking to large and influential audiences of mining men wherever he has gone. He is now on the home stretch of his long journey, having reached Canada by crossing the Pacific, after visiting Africa, Asia, Australia, and New Zealand. He has seen the mines of British Columbia and Alberta, and a few days ago came to Toronto after seeing the nickel, silver and gold districts of Northern Ontario.

On the invitation of the Toronto Branch of the Canadian Institute of Mining and Metallurgy Mr. Marriott addressed a meeting held in the Convocation Hall of the University on Friday, Nov. 23rd. When the Provincial Geologist, Dr. W. G. Miller, who was chairman of the meeting, led the procession to the platform, it was seen that, as he expressed it in introducing the speaker, "there were present on the platform three distinguished representatives of British mining industries,—Mr. Marriott from the heart of the Empire, the Hon. Mr. McCrea, Minister of Mines of the banner mining province of Canada, and Mr. John Dresser, President of the Canadian Institute of Mining and Metallurgy."

Canada's Influence in Other Dominions

Continuing his introduction, Dr. Miller said he knew a great deal about Mr. Marriott, most of it good. Mr. Marriott had been one of the representative mining men conducted throughout Canada fifteen years ago, and he (Dr. Miller) had had the pleasure of travelling with him at that time. He had also seen him in South Africa where Mr. Marriott had exercised a potent influence not only on mining methods but on the mining policy of the country. At Mr. Marriott's suggestion he had called on General Smuts, who at once asked him questions about Canadian experience with bounties on iron and steel. This inquiry emphasized the way in which the other British Dominions are watching Canada, seeking to learn from and profit by our experience. He learned that South Africa is studying the work of Ontario's Hydro-electric Commission to get hints on transmission of electrical power. South Africa is building great grain elevators, and the contractor is a young Canadian who got his experience in Kingston and Winnipeg. All of this went to show that the British Dominions are being knit together not only by the bonds of sentiment but also by those of industry. And the aim of the speaker of the evening was to promote the latter particularly in connection with mining and metallurgy.

Mr Marriott's Address

Mr. Marriott, a well set up Englishman, who carries lightly his half-century or so of years, spoke of his long experience in the mines of South Africa and of his retirement lately to his farm in Northamptonshire, an inheritance coming down in his family from the time of Henry VIII.

He wished to speak of things that really matter from the Empire point of view. The thing that impressed him most is the value of personal intercourse between the units of the Empire. Difficulties disappeared and unexpected advantages came into view when men got together. That was why he was making this extended tour round the world through the British Dominions.

Value of Inter-Imperial Intercourse

The value of intercourse among representative men was illustrated by the Pan-Pacific Congress. With headquarters in Honolulu, this organization discusses the interests of the countries in and bordering on the Pacific Ocean. It is quietly bringing about a great many improvements in industrial and living conditions. It has been so effective in this respect that it is more than suspected that some of its large projects are being partly financed by governments interested in the improved conditions.

In discussing the recent work of this Congress, Mr. Marriott had occasion to refer to the great organizing ability shown by Dean R. W. Brock of the University of British Columbia. The Australian geologists have done fine work in tracing the geological features for the location of artesian wells, as part of a great scheme for the irrigation of dry belts. The study of communication by radio has been joined in by Japanese, Filipinos, and other eastern nations, and it has developed that there may be a good chance of getting in this way useful forecasts of typhoons and earthquakes. Within the next ten or fifteen years radio-telephony will be so perfected as to knit together the whole empire more effectually than any other advance in science.

In New Zealand much hydro-electric power is being developed, and it is being used freely. For example it is not unusual to see a conducting line several miles long in the country supplying only a two H. P. motor. On these New Zealand farms the cows are milked by machinery. Formerly oil-engines were used, but the farmers say the cows like the gentle purr of the electric motor better than the jug-jug of the engine, and so give more milk.

Canadian Society is Top-Heavy

Mr. Marriott knows Canada fairly well. He admires our very fine organizing ability,—but finds that while we are well organized at the top, we have neglected the bottom—the base of our social structure. Canadians take great pains to educate and provide for the few who do the thinking, but are not so careful to see that the multitude have the best chance for a satisfactory existence.

If Canada wishes to get the farming lands and the mining communities settled by men who will stay and be satisfied, she must take more pains to see that they have the ordinary means of a social life,—such a life as is possible only where there are well organized communities. "Give them a bit of what they are, want or are used to, amusement halls, radio, cinema, music, football, and so on. Then they will stay in the outlying places and not overcrowd the cities."

Opportunities In Canada

In studying the mineral resources of Canada, the speaker was impressed with the unlimited supply of coal in the West. In Alberta, where the mining conditions for coal are unusually favorable, he was told that it could be taken out for $2.00 a ton, if labor conditions were normal; but Canadians are allowing foreign control to run up the price of our own coal to such an extent that we cannot afford to transport it any considerable distance from the mines. In his opinion this state of affairs was greatly retarding the development of Canadian manufactures and other industries. "The way to get ahead is to be self-contained. Cheap coal means cheap power for industries

With that we might have as dense a population as in Belgium."

Canada is the great unoccupied space into which the human race will expand. Let her be afraid to receive no race of real workers. The more men, the better chances for finding among them that peculiar, keen observant type that makes the best prospector. Mineral discovery is difficult and so attracts men of fine characteristics. The indications are that, as time goes on, the prospector will be a man of scientific bent and education.

Ontario is likely to have a greater and steadier mineral development than any other part of the world, and to speed up that development, there is needed the hearty co-operation of prospector, miner, manager, and investor. —each enjoying his share of the work, and each getting enough out of it to give him a contented life.

Mr. McCrea Says All Must Work

The Hon. Mr. McCrea, in moving a vote of thanks to speaker, referred to Canada's lack of organization at the the bottom. We have boundless resources and the possibility of a good living and a satisfactory life for all; but owing to faulty education and other removable causes, everybody wants to be at the top. The educators have given much thought to this subject and will find a way to impresses the fact that spade-work is for us all. We must be workers, the development of natural resources must be wisely and strongly pushed, we should tell the world what we have, and investors should be assured of the stability of our mining laws, and of fair treatment in respect of titles and taxation. During his life in the north country he had felt that our future lies in the expansion of our industries, mining as well as agricultural. He paid a well-deserved tribute to the team work of the Deputy Minister, Mr. T. W. Gibson, and the Provincial Geologist, Dr. W. G. Miller. At the present rate of increase the value of the mineral products of Ontario will have attained in twenty-five years from now to 1,500 million dollars.

The great Empire Exhibition of 1924 should do much to forward Mr. Marriott's idea of co-operation in the mineral development of the Empire. It is to be hoped that at the same time something may be done to bring up Canada's coal, oil, and iron ore production to the favorable position shown by her output of nickel, silver, and gold.

Mr. Dresser Honors the Pioneers

The President of the Institute spoke of Mr. Marriott's part in initiating the Imperial Mineral Resources Bureau, of which Dr. Miller is an influential member. Doubtless the idea now being worked on by Mr. Marriott was an outcome of the activities of this Bureau, namely, an Empire Mining Council to connect all its mining and metallurgical societies. Mineral industries will progress in proportion to the increase in our knowledge of our country. To this end we need many explorers and improved transportation, and more appreciation of the pioneer's work by those who conduct the business of the great centres of population. Mr. Dresser cited the case of Toronto, attributing a great part of its recent growth and prosperity to the development of the mineral and agricultural industries of the north. The pioneers who hesitantly built the railway that made possible this development should be suitably honored and remembered.

NEW ARCTIC MAP

The Geological Survey, Ottawa, has issued Map No. 1963, showing the geography and geology of the Arctic coast on both sides of the Coppermine River for a distance of 200 miles, on a scale of 10 miles to the inch. The area has large tracts underlain by pre-Cambrian rocks, as well as Silurian and later series.

NEW USES FOR SILVER.

Systematic study of silver and its alloys should result in its wider use in at least two fields, with strong probability of similar results in other directions, according to a report submitted by the U. S. Bureau of Mines to Secretary Work of the Interior Department in response to his recent request for a preliminary study of possible new uses for silver in commerce and industry. The possibility of developing a non-tarnishing silver for use in tableware and the arts and of finding silver alloys suitable for trimming automobiles were set forth as the two fields in which a systematic investigation should result in a wider use of silver.

"Silver has been allowed to fit into places where it would satisfy the requirements, and little systematic research to develop new uses has been done," the Bureau of Mines' report stated. "Such research, therefore, has a better chance of success than if the field already had been extensively investigatel. Although individual producers and fabricators have not overlooked the possibilities of such studies, it is believed that the situation now has reached a stage where, under govermental direction, these individual investigations could be co-ordinated into a systematic plan of research to increase the commercial and industrial use of silver.

"One of the major possibilities would be through the development of new alloys. It is well known that a small percentage, in many cases only a fraction of 1 per cent, of one metal alloyed with another changes the properties of the latter greatly. Everyone is familiar with the decided change in appearance caused in copper by the addition of a small percentage of nickel, as well as with the decided change in properties of steel caused by the addition of very small percentages of non ferrous metals. It is entirely possible that a systematic investigation would develop alloys of silver which would have most desirable properties for use industrially or commercially.

"One of the chief drawbacks to the use of silver for household articles it that it readily tarnishes. If this could be evercome or materially decreased by means of the development of an alloy which would not be excessively expensive, it should result in a great increase in the use of silver articles and, in turn, in a large increase in amount of silver consumed.

"It is known that certain metals, including cadmium, when alloyed with silver reduce its susceptibility to tarnish. This is mentioned merely as an example. It is entirely possible that other metals or combinations of other metals with silver would form an alloy less susceptible to tarnish, if not non-tarnishable, under ordinary conditions.

"There is further the possibility of developing relatively cheap alloys in which only a small proportion of silver will be used which, due to the large consumption of such alloys, would result in a large increase in the amount of silver consumed. Silver-aluminum alloys deserve consideration in this connection. One of the [illegible] which such alloys might be put would be that of trimming on automobiles. A silver alloy relatively non-tarnishable and solid throughout would have decided advantages over the present nickel-plated trim. The investigation of the possibility of producing such an alloy is worthy of consideration."

The Quebec Gold-Field

Present Conditions in Rouyn and Boischatel Townships

(By the EDITOR)

A visit, just concluded, to the active sections of the Rouyn-Boischatel gold area of northwestern Quebec shows substantial progress since last I was in the region in September. Work on the properties that have reached the stage of diamond-drilling and shaft sinking is progressing steadily. At least one new property has been added to the list of prospective mines, and a number of promising prospects have been uncovered as a result of work late in the season. I shall describe these developments briefly. There are bound to be some properties meriting mention that I have not included here; this is merely because I lack information about them.

The Noranda Groups

The first and best known claims are the groups in the northwest part of Rouyn townships held by Noranda Mines. The Powell vein, on which such high hopes were centred a year ago, has been rather overshadowed since intensive prospecting last summer disclosed the huge body of gold-bearing breccia on the Chadbourne group two miles to the south. The fact that Nipissing Mines has taken over the Powell group of claims is sufficient to indicate that the Powell is worth exploring by shaft and drifts. Surface work and diamond-drilling have been the only development on the vein so far. A force of miners has been sent in and sinking will be conducted by hand until the requisite machinery is brought in over the winter roads.

The interest of the Noranda Mines management in their Powell vein was diminished suddenly when the Chadbourne deposit was brought to light. It is on the northern part of the Chadbourne claim, the southermost of the group. The outcrop is a rounded hill, thirty-five feet high, of pear-shaped outline, 600 feet by 300 feet, with the large end southward, completely surrounded by swamp. The whole of this hill is gold-bearing, and the extension under the swamp is as yet undetermined. Five hundred feet to the south trenching shows material of the same variety, with volcanic flows close by.

The ore is unique, consisting of brecciated lava from large blocks down to small fragments, cemented with quartz and carbonates, all being impregnated with pyrite. Payable ore of good grade has been determined in various parts of the hill. A shaft has been put down 50 feet in the ore, and as soon as the winter roads allow of moving the heavy machinery from the Powell claims, it will be continued to 150 feet and lateral work pushed in all directions to delimit and explore the ore-body. Should the vertical extension of the ore and its value correspond to the outcrop, a mine of large dimensions will be assured. What is hidden by the swamp, only underground development will determine.

Diamond-drilling continues on the Horne claims, east of the Powell and Chadbourne groups, with one drill. One or more drills in addition will be used to block out the bodies of copper-gold ore indicated at present by the outcrops and two drill holes. The ore disclosed so far is of good smelting grade.

Pelletier Lake Prospects

Exploration on the above three properties is being conducted on a comprehensive scale, with the expenditure of considerable sums of money. The other discoveries in the township of Rouyn are mostly in the hands of the prospectors and, though some have done a considerable amount of test-pitting, the majority of those who have done any work on their claims have confined themselves logically to stripping and putting in pot-shots for samples. Most of these are close to Pelletier Lake.

It is interesting to notice, incidentally, the nnmber of claims upon which visible gold has been found. The original gold vein of the township is that found on an island in Pelletier Lake. On the Davies and Lyman claims on Pelletier Lake and on the Gamble (Spry) and Walker claims south of the lake, visible gold has been found, in addition to encouraging values on assay. A considerable amount of work was done on the Bruce (Agnes Ketchen) claim, east of Pelletier Lake, half way to the Kinojevis River, following the discovery of free gold. Visible gold has been found also on the Rouyn Gold claims on Pelletier Lake — the only claims, by the way, that have had so far the questionable attentions of the mining stock broker. Further afield, free gold has been found on the Bailey claims, two miles northeast of Osisko Lake. Gold has been observed in the Powell vein as well as in the Hammill vein, which may possibly be its extension. Veins on the Horne have the same encouraging symptom, while the Chadbourne hill has it quite obviously. One should mention also the Ruth Cockeram claim, east of the Powell, where good assay values in strong quartz veins have been found, and the Bert MacDonald (Gus O'Donnell) showing northeast of Pelletier Lake, where a good deal of work has been done on a wide and persistent quartz vein.

It is not to be expected that all the above showings will make mines; in fact it is certain already that some of them will not. But it is interesting to find so widespread a distribution of the gold in this section, which will encourage the intensive exploration upon which most of the valuable discoveries inevitably depend.

Lake Fortune

Boischatel township, adjoining Rouyn on the west, is at present the scene of a "rush" of township proportions, due to a tardy recognition of its value as prospecting ground. The most important property so far is the Lake Fortune whose gold-bearing schisted zone has been described at some length in these pages. A 150-foot shaft has been started in this zone and is expected to be finished by the end of the year, when extensive lateral exploration will be pushed ahead. Until this underground work shall have proved up an ore-body of mineable proportions and value, we can only hope that the promise of the phenomenal surface showing will be fulfilled below ground.

The Arntfield Find

It is on account of a property a mile and a half to the east, however, which has no spectacular ore so far

disclosed that the present local excitement has originated. On the Arntfield property, comprising 2,000 acres, there has been found a schisted zone very much like that on the Lake Fortune property. It was located less than three months ago and its examination has been merely commenced. So far the whole of the schisted zone, which is 150 feet or more in width, has shown low values, and a thirty-foot section is workable ore. The schist is impregnated with carbonates and pyrite, is cut by quartz stringers, and in places is silicified. There are two smaller schisted zones parallel to this at a distance of 200 and 600 feet, which also show encouraging values in the few samples taken so far. The strike of these zones is N. 60 deg. W. and their dip 65 deg. to 70 deg. to the north. The enclosing rock is lava. Further surface work is under way, and it is intended to sink a prospect shaft to 150 feet depth and to drive exploration drifts and cross-cuts during the winter.

Summary

To sum up: There are already, as a result of this first season's work, five properties that have sufficient evidence of ore on the surface to warrant underground exploration. The Chadbourne and Lake Fortune shafts are already under way. The Powell shaft will be started soon, and the Arntfield shaft will probably be commenced early in the New Year. Underground work at the Horne is still confined to diamond-drilling.

The striking feature of the season's prospecting work is the fact that, almost without exception, prospecting parties that have applied themselves seriously have found gold, either visible or on assay, and that in several cases these finds promise to be workable ore-bodies. Only a small part of the favourable ground in these two townships has been worked over as yet. It is, therefore, quite possible that when all this ground has received the attention it deserves, there will be a line of gold mines, where now there is only a prospectors' trail, from Lake Opasatika to the Kinojevis River.

Letters From Readers

Canadel and Canadian Gold Mines Corporation

To the Editor,
Canadian Mining Journal

In the issue of the *Canadian Mining Journal* of November 16th, on page 904, under the signature of Alexander Gray, is a statement headed "Canadel - Oh Canadel". Mr. Gray severely criticises the company and the methods of its financing.

In order to set him right I desire to state the following facts: The shares of the Canadel Gold Ltd., to which Mr. Gray refers, are all owned and in the possession of the Canadian Gold Mines Corporation, the Canadel Company being merely an operating company.

The Canadian Gold Mines Corporation has never represented that it owns the Rochester Mine. It has the property under option, has made all the payments to date and has funds on deposit to meet all future payments when they fall due. The company has expended in development in the neighborhood of $250,000, and is a bona fide institution which is developing the Rochester and 52 other mining claims in Porcupine which it owns in fee simple, without regard to the stock markets. The Canadian Gold Mines Corporation has never issued a public prospectus, has never publicly offered its shares, and has never permitted these shares to be quoted on any Stock Exchange here or abroad. The stock has been fully subscribed by substantial people in England and no attempt has ever been made by the present owners to interest the outside public in its shares in either England, the United States or Canada.

THE MACKENZIE COAL REPORT

To the Editor,
Canadian Mining Journal

In his letter, appearing in your issue of November 9, Mr. C. M. Campbell seems to have missed the point of my letter, which appeared in the *Journal* of October 19.

I took up the cudgels in defence of the association that the press, daily and technical, had failed to take notice of the late J. D. MacKenzie's memoir on "The Coal Resources of South Vancouver Island," on the ground that the memoir was then — and, so far as I know, still is — unpublished. The mimeographed copy to which Mr. Campbell refers and which I received with Mr. Wyatt Malcolm's letter (referred to in my previous letter) was palpably from its very nature an advance copy for limited circulation. As to whether it was or was not issued to the press, I am as ignorant as Mr. Campbell, but I am inclined to think it was not. Perhaps you, Mr. Editor, will inform us whether you received a copy. My point, therefore, was that the memoir, not being published in the generally accepted sense of the word, could not very well be reviewed.

Mr. Campbell's reference to my letter in your issue of December 22, 1922, in which I made reference to Mr. MacKenzie's re-valuation of the coal resources of Vancouver Island, has no bearing on the point at issue. That reference was obtained from a report in one of the Vancouver dailies (I am not sure which) of the paper read by Mr. MacKenzie at a meeting of the local division of the C.I.M.M. It was Mr. MacKenzie's memoir, not his paper read before the Institute, that I was discussing.

I claim, therefore, that my explanation of the reason why the press were silent about the memoir is correct.

Whether or not there has been an effort to delay or to prevent the Geological Survey from issuing the printed edition of the memoir, I have no knowledge. With the exception of a few minor errors, the mimeographed [illegible] imagine that the printed edition should be ready for distribution before this; but I have no idea what the demand has been upon the Government printing department. I noticed, too, that some little time ago the Government was seeking applications for an editor for its mining publications, and it is possible that shorthanded ness in this department may have caused delay in publishing the memoir.

Victoria, B. C. E. H. Mason

[illegible] not receive a copy of the mimeographed report to which Mr. Mason refers.

The Future of our Mineral Industry

Dr. Corless holds that we must envisage the future greatness of our mineral industry if we are to attain to it.

To The Editor,
Canadian Mining Journal,

I am in hearty accord with Mr. C. M. Campbell's commendable zeal for economy and sanity in the development of Canada's natural resources. I am equally in accord with his desire for conservation of these resources, meaning by the latter term such wise use as will contribute the maximum benefit to the human family. I approve, also, of his criticism of inordinate, foolish or inconsiderate expenditure of money, whether public or private, either for development of these resources or for any other purpose whatsoever. Our financial difficulties have not arisen from lack of natural resources but they have been caused, in some cases at least, by lack of sanity in the time, or the procedure, or the methods selected, in developing them. I have no intimate knowledge of the P.G.E. Ry. in British Columbia. Assuming the correctness of the statements made in regard to it, I would call it sheer insanity to build such a road before investigation of the potential traffic, mineral or other, that would be contributory to the projected line.

Long residence in Northern Ontario and an intimate knowledge of the conditions in the pre-Cambrian, as far as these are at present known, have convinced me that, in spite of the important mining developments of the past twenty years, we have scarcely glimpsed the mineral wealth of this vast area. Nevertheless, no one would oppose more quickly or more strongly than I, the building of a railway at random in this area, on the supposition that it would be certain to tap sufficient deposits to make it a financial success. I can find no statement of mine either before the Institute or elsewhere, that lends any color to the implied inference running through Mr. Campbell's discussions, that belief in the vastness of our mineral resources would cause myself or any other sane man to favor any such method of development. What this belief does justify, what the expression of it in fact, among other things, was intended to encourage, is wisely increased expenditure of money on exploring, geologizing and intelligently prospecting Canada's great hinterlands.

There is a sane and proper order which should be followed in opening up and developing a great mineral area, such as the pre-Cambrian or the Pacific Highland. This order is a matter that has lain outside the province of my discussions so far. If this order, which may differ considerably in different localities, is not followed; if some of its steps are omitted or reversed; the outlay always incidental to mineral discovery and development is inevitably increased. This class of work is costly at its best. It has its own special risks. But that is no reason for timidity. Careful, and usually expensive, investigation along wisely chosen lines is generally necessary in discovering and proving up a valuable mineral deposit. But the man who is unwilling to accept the responsibility of coming to decisions on these matters, or who dwells on the well-recognized difficulties of this class of work and lets them dampen his courage, should choose some other profession than mining engineering. He may be a success at systematically and efficiently extracting ore from a mine but he will soon be without a mine to operate. I should be very sorry, indeed, if the fact, that the topic I chose for discussion before the Institute did not include these perhaps equally important matters, caused any considerable number of my fellow engineers to think that I have no sense of the care required in discovering and opening up our mineral resources. I have at times been called ultra-conservative on this very matter.

But the prime necessity is to establish by sound reasoning that we have these mineral resources, for, because of their hidden nature, no other course is open to us, direct observation being impossible. This is one of the reasons, though not the only one, why, as I have repeatedly pointed out, mining, as an extended business in a new country, is at first slow in coming into its own. Generally, a number of well-exposed mineral deposits are easily stumbled on, usually quite early. These are worked and the conditions of their occurrence are observed. These observations form the basis of induction, perhaps unconsciously, at first. Gradually technical men, and later the public, come to recognize the place of mining as a basic industry of real importance. It is well for us not to lose sight of this later arrival of mining in the natural succession of basic industries. Otherwise the valuable statistics Mr. Campbell has furnished from time to time may be misinterpreted.

So far as one can see, we appear at present to be passing through the transition stage from spasmodic to systematic exploration, development and mining in my own province. To attempt to judge the future of mining in Canada by our past, as Mr. Campbell does, is like attempting to predict the future farming output of the Peace River District by its past production. Very little of our pre-Cambrian territory has even been run over, much less geologized or prospected. Geologizing and thoroughly prospecting our vast mineral heritage will be the work of centuries, not of decades. Forty years has almost certainly not sufficed to find all the ore deposits even in so limited an area as the Sudbury copper-nickel district. Only a few of them have yet been explored, by drilling, to more than 1,200 feet depth. The work of development and mining in a district nearly always reveals fresh clues which, if keenly observed and assiduously followed up, lead to further discoveries not only in the mine itself, but in its locality. The following up of such clues, the introduction of new methods of search, and improvement in technical processes for mining and recovering metals, usually greatly prolong the life of a mining district.

To illustrate: Improved equipment, organization and processes have made mines of the so-called western "porphyries". Sullivan's problem has been solved, to the great credit of the staff at Trail, and this doubtful proposition has become a splendid mine. Even financially mis-handled Rossland is not dead yet. The "Boundary" appears to be an exception. It is hard to believe that even there none of the dozens, or even hun-

dreds, of promising claims will yet come into production or that no further discoveries will be made. Developments at Hollinger, Dome and McIntyre-Porcupine mines revealed geological clues that are greatly extending mining in this camp. So also at Kirkland Lake. The early mines at Cobalt revealed clues that assisted the later ones, and the camp as a whole led the way to Gowganda and South Lorrain. As the Astronomer improves his telescope and other appliances, more stars come into view. As the Mining Engineer increases his knowledge of applied geology and improves his prospecting methods, his technique of mining and ore reduction, and his organization of both brains and energy, more ore reserves are made available.

I have no hesitation in answering Mr. Campbell's categorical question, in your issue of October 19th, affirmatively. I do believe absolutely and literally in the correctness of the statements I made in my Presidential Address regarding the extent of Canada's mineral resources. I believe further that the reasoning employed in reaching the general conclusion regarding the vastness of Canada's potential wealth in minerals is absolutely sound and cannot successfully be attacked. In this belief I know that I do not stand alone. If any considerable number of my fellow members of the C. I. M. M. feel, as Mr. Campbell appears to do, that the position of President was abused during by tenure of office, by the frank statement of my belief in the vastness of Canada's mineral wealth — expressed with as full grounds for the belief as limited time permitted, and prepared with a view of assisting Canadians to grasp more clearly the future relative importance which the mining industry in Canada is certain to assume—, I deeply regret it.

But this will not change my personal view that the mining engineer owes it to his fellow citizens to make these facts known. This, especially in a time of financial crisis such as the present, is only a first step. He owes it equally as a public duty to try to direct public policy sanely toward their development.

This second duty, I believe, Mr. Campbell is trying to discharge. But, in my judgment, the best method of doing this is not along the course he is pursuing. It does not consist in denying that Canada has vast potential wealth in minerals, nor in deploring belief in this as "the worst thing that has ever cursed this country," but rather in the more active policy of seeking to guide our statesmen and others concerned in their development, by sound advice, based on our experience as mining engineers, as to how to discover, develop and recover these minerals with least public and private expenditure and loss. But, if we do not believe that this vast potential wealth exists; if, as Mr. Campbell is doing and as he has stated it to be his determination to continue to do, we denounce this belief at every opportunity; if we regard the determination, skill, hard work and expenditure of money, required to overcome the difficulty of discovering and proving them, as amounting in some way to proof that we have not got them; if, in place of offering advice and encouragement we almost gleefully flaunt our disappointments, which, in prospecting for and proving up ore deposits, will always be many for every real success achieved; then a far larger part than necessary of our mineral wealth must remain undiscovered; and our heavy public debts, due to a great extent to the war and arrested development resulting from it, will press all the more heavily on the shoulders of our remaining industries.

Canadians are now just beginning a new campaign in the effort to open up and settle our great unpeopled areas. The arrest of immigration due to the world struggle appears to be coming to an end. Never has it been of more vital importance that we should, by every possible means, try to grasp the relative extent of our resources. In the case of lands and forests, this is comparatively easy. It is more difficult in the case of minerals. But Canada's great areas from which minerals will be the chief, and in some cases possibly the only, natural resource to be recovered; her climatic limitations; her relatively restricted land areas suitable for cultivation; the advisability of balancing her industries and thus creating home markets for her farm products, now so seriously handicapped by high transportation costs to distant markets—these are some of the factors that make it of supreme importance that our public men should be informed as to the place the mining industry may be expected to occupy in the future development of our country.

As to the quibble Mr. Campbell has tried several times to raise as to whether this or that word is best to use in order to express the ideas I wished to convey, I do not feel justified in taking up your valuable space, and the time of your readers, in a further discussion of this matter. My belief is that my hearers and any subsequent readers, who considered the address without prejudice, generally found no difficulty in discerning the meaning intended; with this I am satisfied. The conviction of the truth of the statements made has been formed in my mind slowly, as a result of nearly twenty years' observation, study and experience and cannot easily be shaken. It was a mature, and not hastily formed, judgment. Moreover, it was a conclusion arrived at in my own special field of work. I accept fully every responsibility involved in expressing it. A short period of exceedingly successful mining development, such as we are now enjoying, or a short period of reverses, would not alter my judgement as to our country's vast mineral resources. If Mr. Campbell has had his attention too closely confined to the "Boundary" of British Columbia or to the coal resources of Vancouver Island, to permit him to study carefully the potential mineral wealth of the remainder of Canada, and, if this experience has affected his judgment, the failure to grasp the greatness of Canada's wealth in minerals is a natural result. But it becomes a very serious matter when he expresses it as his intention to denounce belief in the vastness of our mineral wealth, in view of our known resources in coal, nickel, silver, gold, copper, lead, zinc, asbestos, iron, not to mention gas, oil, clays, building and cement materials and numerous others already discovered in the small fraction of our half-continent that we have barely begun to prospect. This will prove to be not only a fruitless but a thankless task, because it is flying in the face of common sense and reason.

But if he will divert his denunciation to improper, useless or wasteful methods of seeking, developing and recovering this mineral wealth, he will be backed by the judgment of every mining engineer giving serious [illegible]

C. V. CORLESS

Coniston, Ontario.

A Bureau of Steel Manufacturers has been formed in Australia to forward the common interests of iron and steel producers in the Commonwealth.

THE MODERN CHANGE-HOUSE

Data acquired in a survey of change-houses at mines in the Lake Superior iron and copper region are presented in Technical Paper 289, just issued by the United States Bureau of Mines.

When the mining industry was yet in its infancy, the miners changed their clothes at home, leaving the mines after work — dirty, tired, and often in clothes saturated with body excretions, a custom inconvenient and resulting in much ill-health, states Cleve E. Kindall, formerly acting assistant surgeon, U. S. Public Health Service, detailed to the Bureau of Mines for this and similar investigative work. Many miners found it more satisfactory to change their clothes in the boiler rooms. As the industry grew, the mining companies realized that change houses must be provided. These were mere shacks at first, but the modern change house was developed from these unpretentious beginnings. Even now some of the old inconvenient buildings are still in use.

A modern change house at a progressive mine has washing, bathing, and latrine facilities; here employees may change their clothes before and after work. Adequate bathing facilities are especially important at a mine whose ores are soft. Efficient drying equipment should be supplied if there is considerable moisture. Mine foremen and shift bosses at many mines in the Lake Superior region have offices in change houses. One of these offices may be utilized by the timekeeper when checking the men on the various shifts. The posting of safety-first notices and first-aid bulletins on the walls, a common practice in many change houses, is to be commended; in this way they add to many other functions that of agencies for spreading valuable information among the men.

The number of change houses in the Lake Superior region has increased steadily. Approximately 100 companies were operating about 500 copper and iron mines at the time this report was written. The Bureau of Mines investigator examined about 25 per cent of the change houses at these mines, and found many old houses still in use. Since mine operators have discovered that health and efficiency go hand in hand, however, the buildings and equipment have been improved noticeably. This improvement is most marked in the change houses built within the last five years.

A majority of the change houses investigated were of the most modern type, built of brick, stone, or concrete, and roofed with tile or rubberoid. The old buildings were made of wood or corrugated iron. The wooden buildings had roofs of wooden shingles, tar paper, or corrugated iron; and the corrugated iron buildings had roofs of the same material. A structure of concrete blocks or brick, roofed with tile, is recommended. If a material other than tile is used for roofing, it must be noncombustible.

Accessibility to the shaft is an important feature to be considered in the placing of a change house. A few of the change houses noted were built as far as three-fourths of a mile from the shaft, a condition that is dangerous to the health of employees. Men who have been laboring hard underground in a hot, damp atmosphere are very susceptible to colds and pneumonia if exposed to a sudden drop in temperature. This is especially true in the Lake Superior region, where climatic conditions are extreme.

A modern change house that attempts to meet the peculiar needs of the Lake Superior mining industry has been designed by Dr. Kindall and is described in this paper. Practicability, convenience, economy, and sanitation are the ideals that should be incorporated into plans for a modern structure. These ideals were both expanded and modified after an investigation of some of the largest and best plants that manufacture change-house accessories.

ELECTRICAL PROPERTIES OF PERMALLOY THE NEW NICKEL ALLOY

An alloy of nickel and iron has recently been developed which, it is anticipated, will multiply several times the speed of trans-Atlantic cable transmission. In reporting the unique magnetic properties of this metal to the American Physical Society, Dr. H. D. Arnold, director of research of the Western Electric Company, heralded the invention as the greatest development in submarine cable practice since the invention of the siphon recorder by Lord Kelvin.

The new metal, to which the name "Permalloy" has been given, is composed of nickel and iron, the best proportions being about 80 per cent. nickel and 20 per cent. iron. When subjected to a special heat treatment it is distinguished by extraordinarily high magnetic permeability at low magnetizing forces. In some samples that have been tested, permeabilities two hundred times as great as that of the best iron have been obtained. It is the most easily magnetized and demagnetized of all magnetic materials. This gives it remarkable value in such applications as that of the submarine telegraph cable, where large magnetic effects are desired from extremely small electric currents. It is expected also to be valuable in the art of telephony.

A peculiarity of permalloy is its sensitiveness to mechanical forces, the permeability changing greatly when the material is stretched or otherwise strained, without exceeding its elastic limit, and regaining its usual value when the force is removed. If, however, such a force is exerted upon it that the elastic limit of the material has been exceeded, a renewal of the heat treatment is then required to restore its previous permeability characteristic.

No explanation was offered for the alloy's remarkable magnetic property. As determined by X-ray analysis, it has the face-centered cubic arrangement characteristic of nickel crystals, rather than the body-centered arrangement characteristic of iron. Small quantities of chromium or cobalt do not affect it to a great extent but a minute quantity of carbon adversely affects its magnetic permeability.

Thus there is added another to the already extensive list of nickel alloys used for electrical purposes.—from *Inco*.

THE QUEENSLAND SILVER-LEAD FIND

Further reports from reliable sources have now been printed regarding the new and important silver-lead find in Queensland, Australia. It is 26 miles due north of Chillagoe, but the road to it is 47 miles long. The outcrop is approximately three-quarters of a mile in length and ten samples taken from sections 100 feet apart have averaged from 52 oz. to 70 oz. of silver and 50% lead. Values throughout the lode as at present determined are of markedly regular distribution. It is hoped this find will lead to a revival of mining in North Queensland.

Ontario's Metalliferous Production -- First Nine Months, 1923

Prepared by W. R. ROGERS, Statistician

Returns received by the Ontario Department of Mines from the metalliferous mines, smelters and refining works of the Province for the nine months ending Sept. 30th, 1923, are tabulated below, and for purposes of comparison the quantities and values are given for the corresponding period in 1922. Tons throughout are short tons of 2,000 lbs.

Product	Quantity		Value $	
	1922	1923	1922	1923
Gold, ounces	749,631	705,183	15,506,896	14,577,315
Silver, ounces	7,560,301	8,604,543	5,609,625	5,632,560
Platinum metals, ounces	113	950	7,771	92,430
Nickel (metallic), tons	3,491	8,337	2,012,539	3,268,871
Nickel in matte exported (*)	2,927	6,962	1,595,500	2,784,800
Nickel oxide, tons	235	4,275	81,160	1,224,091
Nickel sulphate, lbs.	27,270	.....	2,231	.....
Cobalt (metallic), lbs.	22,173	210,176	60,932	531,699
Cobalt oxide, lbs.	293,364	327,912	589,883	638,969
Unseparated Cobalt-Nickel oxides and residues, lbs.	1,002,936	481,049	218,556	182,305
Lead, pig, lbs	2,593,888	3,291,518	147,698	214,644
Copper sulphate, lbs.	22,553	.....	1,310	.....
Copper (metallic), tons	1,052	5,055	245,489	1,523,412
Copper in matte exported (*), tons	3,191	4,368	526,860	873,600
Iron ore (**), tons	4,304	7,594	25,261	26,452
Iron, pig (***), tons	12,296	9,543	291,926	231,496
Total	.....	.....	26,923,637	31,802,644

* Copper in matte valued at 9 and 10 cents per pound and nickel in matte at 25 and 20 cents per pound in 1922 and 1923 respectively.

** Figures in the table cover shipments to points other than Ontario blast furnaces.

*** Total output of pig iron from both domestic and imported ore was 550,355 tons worth $13,350,398. Figures in the table represent proportional product from Ontario ore.

General Remarks

The total value of metalliferous production for the nine months under review exceeded that during the corresponding period in 1922 by $4,879,007 or 18 per cent., thus demonstrating the strong position which Ontario's metal mining industry occupies at the present time. Gold production shows a small decline due to power shortage during the first quarter of the year. This is explained under the heading "Gold". However, if production for the last quarter of the year equals that for the third quarter, the full year 1923 will show an output of over $21,000,000 as compared with $20,374,109 in 1922.

The total output of silver shows an increase of over one million ounces. A revival of interest in this metal has resulted from the mining of rich ore in South Lorrain.

The nickel-copper industry is back again on a pre-war basis of output, with the difference that the main outlet for products has switched from armament purposes to industrial uses. Details regarding the several metals are given under separate headings.

Gold

Ontario's production for the third quarter of the year was at the rate of 95,566 ounces per month. Power shortage, as already stated, seriously interfered with production early in the year. This condition was remedied by the addition of two new hydro-electric plants on the Mattagami and Montreal rivers. These are now supplying power to Porcupine and two other large power plants are under construction on the Abitibi and Quinze rivers to meet present and future requirements of northern Ontario's mining industry.

Night Hawk Peninsular is scheduled to begin milling operations with a 150-ton plant before the end of November and the Vipond Consolidated (150 tons) is expected to start milling before the end of the year. On several other promising properties in the Porcupines and Kirkland areas development is under way.

The Argonaut mine in Gauthier township commenced milling operations in July. The ultimate milling capacity is 200 tons. Croesus in Munro township is being operated again. It is equipped with a 15-ton amalgamation mill to treat the rich ore found on the property. On the Crown Reserve and Associated Goldfields properties at Larder Lake, large ore bodies are being blocked out. Development is proceeding at Matachewan, West Shining Tree, Lightning River, Schreiber, Boston Creek, Painkiller Lake and other promising areas. That the pre-Cambrian gold areas of northern Ontario are rich both in performance and possibilities is evidenced by the widespread attention they are attracting both in America and abroad.

Details of production for the period under review are given in the table on the following page.

In addition to the value of gold noted in this table, Ontario producers received for their contribution to the Dominion Smelting Bonus [illegible]

Crude gold bullion received at the Royal Mint, Ottawa, from Ontario mines [illegible] and amounted [illegible] fine ounces of silver.

Nickel and Copper

[illegible] producing therefrom 41,996 tons of nickel-copper matte. Exports of matte to Clydach in Wales and Huntington, W. Virginia, totalled [illegible] were further treated in the refineries [illegible]

Source	Ore Milled tons	Gold Output ounces	Gold Output value $	Silver Output ounces	Silver Output value $
Porcupine

of the two first-mentioned companies, located respectively at Deschenes, near Ottawa, and at Port Colborne on Lake Erie. From matte refined in Canada with the exception of a small recovery by Ontario silver refineries, copper, nickel and nickel oxides as noted in the table were produced. In addition 589 ounces of gold and 37,386 ounces of silver were recovered, also metals of the platinum group including 371 ounces of platinum, 499 of palladium and 80 of rhodium and iridium.

The nickel and copper contents of matte exported have been given an arbitrary valuation in the table of 20 cents and 10 cents per pound respectively. The average New York price of electrolytic copper for the period was 14.99 cents per pound, while average electrolytic nickel prices as given by the producers vary from 23¼ to 28 cents per pound.

Silver

It is gratifying to report a marked increase in silver output. Cobalt began production in 1904 and reached its zenith in 1911 when 31,039,104 ounces were shipped from Cobalt and outlying silver areas. Now the South Lorrain camp, some eighteen miles to the southeast, has revived and is attracting attention owing to the excellent results obtained at the Keeley and Mining Corporation of Canada mines. These properties shipped 2,286,290 ounces of silver during the period, in addition to high grade cobalt ore and residues. Silver operators were paid for 583,246 pounds of cobalt contained in shipments.

The principal silver shippers were: Nipissing, 2,525,913 ounces; Mining Corporation, 1,701,532; Keeley, 1,135,179; O'Brien, 661,934; Coniagas, 618,093.

At the Colonial mine, which adjoins the O'Brien to the southeast, a shaft has been sunk 1,000 feet and good silver values obtained near the lower contact of the diabase sill. High grade shipments are now being made. A new concentrating mill on the Castle Trethewey mine at Gowganda is nearing completion.

Shipments of ore, concentrates and residues over the T. & N. O. railway were 78 cars or 2,866 tons to Deloro in southern Ontario, and 27 cars or 1,086 tons to the United States, principally to Perth Amboy, N.J.

Refineries: The Coniagas Reduction Company of Thorold and the Deloro Smelting and Refining Company treated 1,893 tons of ore and concentrates and 4,479 tons of residues for the recovery of silver, arsenic, copper, cobalt, nickel and compounds of the two last-mentioned metals. Sales of metallic nickel were 34,055 pounds worth $8,590, and of nickel oxide 38,964 pounds valued at $5,044. White arsenic marketed was 1,752 tons worth $395,638. The quantities and valuation of cobalt and compounds, also of unseparated cobalt-nickel oxides and residues marketed, are noted in the table.

Iron Ore and Pig Iron

The only shipper of iron ore was Moose Mountain Limited. Of a total of 24,062 tons of beneficiated magnetite shipped, 16,168 tons went to the Hamilton blast furnace, and its value is included in the output of pig iron.

Blast furnaces at Sault Ste. Marie, Port Colborne and Hamilton, operated 7 stacks for an average of 201 days each. The total ore charged to furnaces was 1,002,089 tons, of which only 17,383 tons or 1.734 per cent. was of Ontario origin. Pig iron output is noted in the table. Steel production was 514,694 tons worth $17,571,268.

Lead

Except for a small recovery from silver ores, the entire shipments of lead, as given in the table, were made by the Kingdon Mining, Smelting and Manufacturing Company with mine and smelter at Galetta on the Ottawa River.

VIKING GAS WELLS SUPPLY EDMONTON

Natural gas is now being delivered in Edmonton from the Viking field, where ten wells are in operation with a daily open flow of 40,000,000 cubic feet. Seventy-seven miles of main line were constructed between Edmonton and Viking and 81 miles within the city. The total cost of the undertaking was about $3,000,000.

INCREASING USES OF SILVER

In these days of scientific salesmanship it is rather unusual that any article of accepted merit shall not increase its sales in proportion to the general increase in business. Intense advertising campaigns and high-grade salesmanship develop greater demands on the part of the public for various kinds of merchandise.

The use of articles formerly classed as luxuries, but which through increased ability to buy have become necessities in almost every line have increased enormously.

It is a startling fact to know that notwithstanding the enormous increase of consumption in almost every other line that the use of silver for manufactures and the arts has practically remained stationary. Were it not for the increased use of silver in photography, in particular relation to the moving picture business, the records would show a very marked decrease in the amount of silver used for industrial manufacturing purposes and in the arts. Iu 1911, 32,013,685 ounces of silver were used in manufactures and the arts.

During the 12 years , 1911 to 1922 inclusive, the average use of silver in manufactures and the arts was 31,922,514 ounces.

Contrast this situation with the total annual volume of business in the United States. For purposes of general comparison it would doubtless be safe to say that this volume of business since 1911 has at least doubled. In this increased volume of business the consumption of other metals and minerals has increased more rapidly than other products. Silver alone of the metals used in industry and the arts has lagged behind.

In no other comparable line of production has consumption been at a practical standstill, and perhaps in no other line has there been so little effort to increase sales by stimulation of public interest, by advertising and through the higher arts of salesmanship. The difficulty has been that silver has been bought and not sold. Silver producers have been unorganized; there has been no concerted effort to show the public the advantages of the use of silver. Substitutes for sterling tableware have taken the place of sterling. Silver tableware manufacturers have changed their patterns so frequently as to make out of date the family silverplate to which additions would be constantly made if mentioned patterns were available.

If the plans proposed by the committee of silver producers growing out of the Reno conference are carried out there is litle doubt but that there will be a very large increase not only in the demand for sterling silverplate, but in other lines silver is used in the arts and industries.—The Mining Congress Journal.

TRANSVAAL PLATINUM DISCOVERY

In the September issue of the *Journal* of the Chemical Metallurgical and Mining Society of South Africa, there is printed a paper by M. Bauman describing a unique occurrence of platinum in the Waterburg district of the Transvaal, which may be of considerable economic importance. Mr. Bauman first describes the ordinary occurrences of platinum in placers, in certain ultra-basic rocks such as serpentine, in ores of nickel and chromium, as at Sudbury, Ontario, and in the Rand banket. Describing the new deposits, he says:

"From the foregoing, therefore, it is evident that the recent discovery in the Transvaal of platinum in a quartz lode in acid country rock extending over a considerable distance is something quite new and quite unique. The lode in question is a brecciated quartz filling in a fault or fracture plane in the felsite of the Bushveld complex. Its location is in the Waterberg District about 24 miles north of the town of Nylstroom and about 100 to 110 miles north of Pretoria. The lode has been traced from a point on the farm 'Rietfontein' 1638, about 10 miles to the west of Naboomspruit Station, in a west to north-westerly direction for a distance of about 20 miles on to the farm 'Doornkom.' The lode matter consists of a brecciated quartz filling with angular inclusions of felsite, Specular iron ore and a highly ferruginous silicate are accessory minerals together with a small amount of chromite. There is much secondary quartz. The unbroken outcrop resembles hundreds of other quartz outcrops in this country. The rock is harder than the felsite, and where not covered by overburden the outcrop stands out prominently above the surrounding country. Freshly broken ore shows a laminated arrangement of alternating bands of white and red or pink, or appears as an agglomerate with sharp red fragments of felsite in a groundmass of white quartz. Up to the present no type of lode matter in particular has been found to carry plantinoid values. Good values have been obtained in the laminated and in the agglomerate variety, and even in pure white honeycombed quartz. The lode itself varies in width from a foot up to 30 feet. In many places the lode exists as two or three separate bodies with intervening felsite. The general dip of the country rock is flat and to the north; the lode itself, however, dips very nearly vertically and probably south.

"Active prospecting in two areas showed platinum in the outcrop. On the farm 'Doornhoek' the lode was found to be very wide (30 ft.), but the values so far have been very low. At 'Rietfontein,' however, where the lode can be traced continuously for 3,000 yards, the outcrop has been trenched and party stripped for a distance of about 400 yards along the strike, and though, of course, many samples were taken which gave little more than a trace, good but erratic results were obtained over this area. It should be remembered that owing to the fact that prospecting has only recently started here, the identification of what might be called the value-carrying horizon in a lode which is very wide in some places and split into two or three bodies in others, is very difficult, and that from the nature of things many samples have been taken where *ab initio* the presence of platinum was unlikely. The following list of some of the better results over this length of 400 yards is interesting:—

Platinoids.			Width
11.0	dwts.	over	20in.
111.5			1st
8.0	"	"	18in.
32.5			4th
51.0			4th
8.6	"	"	12in.
48.3	"	"	9in.
89.5	"	"	9in.

"The last two results came from one exposure of 54 in. width, in which the lode, about a foot below outcrop, was sampled in six sections of nine inches each. The average of the first two sections is therefore 68.9 dwt. over 18in. or taking the other four sections into account (all of low value) 23.3 dwts. over 54in. Even in a gold mine a section giving 1,258 inch dwts. would be considered more than good. The platinum in the ore is generally very fine, though quite coarse, nuggety pieces are sometimes met. The work so far done is in all [illegible] stage of development that not sufficient data have been collected to throw out any hypothesis as to the formation of the lode and the genesis of its metallic content."

CONTINUED EXPERIMENTS ON COPPER LEACHING METHODS

The leaching of complex copper ores continues to constitute the major problem of the Southwest experiment station of the United States Bureau of Mines, at Tucson, Arizona. The work is centered on the development of methods for the oxidation of ferrous sulphate by air containing sulphur dioxide gas, for the manufacture of ferric sulphate and sulphuric acid in the leaching solution. Two methods of application have been worked out: (1) The direct manufacture and simultaneous leaching as brought out in the special drum apparatus developed by the Bureau of Mines (2) the prelminary manufacture of ferric sulphate and sulphuric acid with its subsequent use as a solvent for copper minerals.

In the drum or direct method, the ferrous sulphate is introduced in the pulp entering the drum, at no cost, through the re-use of the solutions when the dissolved copper has been precipitated by iron. The solution entering the drum need contain only 0.3 to 0.5 per cent iron as ferrous sulphate. By control of the percentage of sulphur dioxide in gas entering the drum countercurrent to pulp flow, the percentages of ferric sulphate or sulphuric acid are regulated. With low gas, under 0.5 per cent sulphur dioxide, the process makes for maximum percentage of ferric sulphate, a desirable condition when sulphide minerals are to be leached. A high percentage of sulphur dioxide gas (3 per cent plus) produces a maximum of sulphuric acid, a condition desirable for leaching of the silicate forms of copper. This method should find favor in the leaching of complex ores and tailings when the sulphide value does not warrant an additional flotation operation.

The manufacture of ferric sulphate or sulphuric acid may be effected in three ways: (1) By introducing air containing sulphur dioxide through a porous medium into water or pulp containing the ferrous sulphate to effect a fine division of the air passing into the solution or pulp. The air containing sulphur dioxide may be bubbled through the solution, being admitted by an air jet producing more or less violent agitation of the solution and bubbling of the gas. (2) The air containing sulphur dioxide may be beaten into the solution of pulp by means of mechanical agitators, such as are used in flotation operation. (1) Air may be used, as in methods 1 and 2, and the sulphur dioxide introduced into the solution or pulp in the form of sulphurous acid—that is, a solution containing sulphur dioxide.

Ferric sulphate readily dissolves one-half the copper in the mineral chalcocite and gradually attacks the balance. Action increases as the temperature of solution rises. This method is applicable to dump leaching or vat leaching, and should find favor where the copper is leached in fairly coarse ore.

The manufacture of sponge iron is closely allied with this method of leaching copper, because large-scale operations demand a known source of iron supply. Sponge iron is a favorable form of iron for this work. The rotary furnace developed by the Northwest Experiment Station of the Bureau of Mines is giving satisfactory results for making sponge iron for mill work at Silver City, Utah.

The separation of clear solution from ore pulp by counter-current decantation or filtration finds favor with several operators and probably will win out when the copper content of solution is high.

The precipitation of copper in the pulp and subsequent recovery by flotation is a simple operation, requiring but low installation cost. Its adoption is dependent on high flotation recovery. Results indicate 90 per cent recovery of precipitated copper can be obtained by flotation after preliminary tests necessary to adjust flotation conditions for each individual ore.

MELTING OF SPONGE IRON

Experimental work on the production of foundry iron from sponge iron in the electric furnace, performed by the Seattle station of the United States Bureau of Mines, demonstrated that technically, at least, the process is a success, though large-scale tests are necessary to determine its commercial applicability. Such a process would find application in melting iron in regions remote from blast furnaces, or where establishment of blast furnaces would be impracticable. Sponge iron was melted in batch runs and continuous runs in various types of furnaces, and under both acid and basic conditions.

The type of furnace found best fitted for the continuous melting of sponge iron is a deep pit furnace with a single electrode and a conducting hearth. The main problems solved were: High recovery of iron, clean separation of the slag, obtaining metal of a high-carbon content, introduction to the metal of silicon and manganese from the slag to eliminate the necessity of using ferro-alloys, and, finally, the removal of sulphur. In order to produce the best quality of gray iron, an auxiliary furnace would be necessary to adjust the final composition of the metal.

REDUCTION AND CARBURIZATION IN IRON SMELTING

Observations made in experimental work on sponge iron and synthetic cast iron, performed at the Seattle station of the United States Bureau of Mines, led to certain conclusions regarding reduction and carburization that differ in some respects from prevalent belief. These findings are being further studied. As a result of this work it would seem that it may be possible to produce low-carbon iron from the blast furnace. In order to obtain exact data on the combination of carbon with iron, reduction tests are being carried on with molten iron in contact with solid carbon and with gases. In the course of this work, it was found that gases (methane, acetylene, or carbon monoxide) were valueless for introducing carbon into molten iron, but solid carbon dissolved rapidly.

SASKATCHEWAN'S SODIUM SULPHATE

Progress and bright prospects in the development of sodium sulphate in Saskatchewan, are reported by the provincial Bureau of Labor and Industries. Sodium sulphate recovered from Saskatchewan deposits is now being used in the manufacture of glass at Redcliff and six deposits so far have been investigated by the Federal Department of Mines. Other known deposits not yet investigated by the department number close to ninety.

METAL MARKETS

(Prices in carload lots, f. o. b. Montreal, as quoted by Consolidated M. & S. Co.)

Average for week ending December 4

Electrolytic copper	13.00
Zinc	7.05
Lead	7.87½

THE MINING DISTRICTS

By THE JOURNAL'S CORRESPONDENTS

NORTHERN ONTARIO

Mines a Mathematical Certainty!—A new exploration mpany is being formed in Toronto, known as the nada Gold Syndicate. The scheme is quite an am- ious one, and while some of the high-pressure stock- ling methods are being used, the proposal appears have the merit of sincerity. Prospective purchasers shares receive an engraved invitation to become nders in the syndicate and are assured that the in- ation are being sent only to a select few whose stand- has been investigated, and that the invitations are orded and are not transferable. This is the usual ome-on" stuff, as it turns out that there has been vide distribution of these so called invitations, and some cases a house to house canvass. The capital is 00,000 shares, of which 900,000 are to be treasury res and 100,000 founder shares, the latter being en as a bonus with the preorganization offerings l presumably also to the promoters. The treasury res are to be sold only for cash, the preorganization ering being at $2.00 a share. This offering was to se November 22nd and the next offering is to be de at $2.50 a share. The promoters hope to realize average of $4.00 a share for the 900,000 shares, which mbitious, to say the least. The syndicate claims to e options or contract covering the purchase of nine ups of properties, but says nothing about the price or igations, and places on these contracts what appears e a greatly inflated value to the Syndicate. Neither nything said about who is to pay for the engraved itations, expensive booklets and long distance tele- ne selling expense. The promoters assure them- es and prospective purchasers of shares that success l be a matter of mathematical certainty by taking antage of the law of averages, and that out of 500 perties submitted to them they will acquire three or r mines from which they estimate minimum annual fits, applicable for dividends, of $1,750.000. Un- tunately the finding and development of mines is such a simple matter as the Syndicate organizers m to think, and what appear to be mathematically tainties often go wrong. Altogther the literature the Syndicate appears to be extremely vague on im- tant point and gives the impression merely of high- ssure stock-selling methods. On the other hand, promoters appear to be sincere and there is no stion that properly conducted exploration syn- ates are a benefit to the mining industry.

nconvenient Road Building Methods—Roads to es and mining centres in Northern Ontario are of greatest importance to the operator. To build m the assistance of the Government must be obtain- and while the Government has shown a very com- ndable enterprise in this connection, their methods open to a good deal of criticism. A case in point is road to South Lorrain, which was very badly ded to provide adequate transportation to an im- tant and growing camp. It was, of course, of partic- r importance in the early development of the dis- t, when the great part of the materials for plants and construction ha dto be transported. The operators would have been well satisfied if the road extension to the camp had been built and the present road gravelled. The Government, however, appears to have certain standards which must be enforced, irrespective of immediate requirements, and the road had to be ditched and widened before any metal was put on. There also seems to be a well established delusion among Government road builders in this section that the best material to put in the centre of a road is the sod from the ditches, and as a consequence when the rainy season came this acquired the consistency of a thin jelly. The result has been that this fall, after the Government had been working for the second year on the road, the mines had to transport part of their supplies to South Lorrain by boat. Probably by this time next year there will be a good road, but in the meantime the operators have been put to great trouble and expense on account of poor transportation. On account of the money the government is expending the operators do not feel that they can complain, although they would have been satisfied with a smaller expenditure, which would have provided for their immediate requirements.

Stating Regulation for Gillies Limit—The Department of Mines has handed down a ruling in connection with taking in the Gillies Limit which provides that stakers of claims shall be entitled only to that portion of a block for which they apply. Previous to this some surveyors were under the impression that claim boundaries should be the same as in the unsurveyed territories, where prospectors' stakes govern, while other surveyors were of the opinion that the claims should form an aliquot part of a block. Fortunately this matter has been handled promptly by the Government, which will prevent any further misunderstandings. It was due to this uncertain situation that the dispute arose over the ownership of the big silver nugget recently found in the Gillies Limit.

Mr Marriott in Cobalt—Mr. Hugh F. Marriott, Past President of the Institute of Mining and Metallurgy, London, and one of the most prominent Mining Engineers in Great Britain, has been visiting the mining centres of Canada on his return from the Scientific Congress recently held in Australia, where he was the representative of the British Government. On this trip Mr. Marriott has visited several British Dominions and Colonies, where he has been advocating the forming of an Empire Council of the mining industry and an Empire Federation of Mining Engineers. The proposal originated in the Institution of Mining and Metallurgy, and Mr. Marriott is their official spokesman. It is proposed that representatives from the mining societies of the different countries should meet in London next June at the same time as the Empire exhibition is being held in order that the Council may be properly organized. If the proposal meets with approval, as now seems probable, representatives would be elected from the different countries to the Central Council, which would be so constituted that each country would have the same number of representatives, irrespective of the number of engineers

each contained. Such an organization would provide for the free interchange of ideas and would deal with Empire problems in the mining and metallurgical industries. Its chief aim would be to raise the status of the industry and of the engineers. To bring this about it is proposed to establish a register of mining engineers and metallurgists within the Empire. Qualifications for registration would, in all probability, be similar to those at present in force in the Institution of Mining and Metallurgy, which are probably the strictest of any similar organization. Membership would be divided into three classes, members, associate members and students, with provision for revision at regular intervals. This registration would be published in book form and would be given as wide a distribution as possible in order that those who wanted to employ a mining engineer in any part of the Empire would have no difficulty in finding a man with suitable qualifications. The possibilities of such a proposal are very far reaching and deserve the most serious consideration. From the reception Mr. Marriott has had in the countries and mining centres he has visited, there seems to be little doubt that the proposal will go through.

Porcupine—A number of Dome directors recently visited the property and express themselves as being highly satisfied with the progress being made. Underground developments are exceedingly favorable and the mine has more ore in sight than at any time in its history. The lower levels in particular are exceeding expectations and large bodies are being developed on the 12th level, regarding which there were so many rumors a few months ago. In October the net profits were $230,000, which is greatly in excess of dividend requirements. The directors state that the Dome Extension will turn out to be particularly valuable, although the amount of development work done to date is comparatively limited. This is on account of the fact that so much work has been necessary on the Dome that there has not yet been time to develop properly the Dome Extension. The directors also disposed of recent rumors to the effect that they were interested in adjoining claims and denied that they had any intention of taking up any more ground near them.

At the West Dome Lake a station has been cut at 750 feet, and sinking is again under way. Two more levels will be established, one at 900 feet and the other at 1,050 feet. Officials of the company appear to be satisfied with developments and state that there is no question but that the West Dome is now a mine.

The Vipond mill is being tuned up preparatory to continuous operations, which it is expected will begin in about two weeks. The mill has been put in first-class shape and the capacity increased to 150 tons a day. Mill heads are estimated to run $10. a ton, and, with prospects of sufficient power for the winter, a good profit should be realized.

The McIntyre has declared its 21st dividend, amounting to 5%, payable January 2nd to shareholders of record December 1st. The dividend is at the rate of 15% a year.

Sufficient Power during Winter Months—Officials of the Northern Canada Power Company state that the possibilities of a power shortage this winter have been practically eliminated. The storage basins are all full and water is running to waste at present. The Sturgeon Falls plant, which provides several thousand additional h.p., is in full commission, though there has been n corresponding increase in power demands. It is n anticipated that the demand during the winter wil show any material increase, and the company shoul be able to get through the winter without any dif ficulty. The Quinze power project is ahead of sched and unless altogether unforeseen difficulties arise, th company should be in a position to deliver power fro that source in Porcupine next summer.

South Lorrain—Shaft sinking has again been starte at the Lorrain Trout Lake property, which is under th management of the Mining Corporation. The shaft i down 280 feet, and will be continued to the contact which lies approximately 200 feet deeper. The botton of the present shaft is about 200 feet higher, geologic ally, than the famous 7th level of the Keeley, and th Trout Lake anticipate better results as depth is at tained, although the results to date have been ex ceptionally satisfactory. The Mining Corporation ex pects to cut the Woods vein on the 5th and 6th level some time in December. This development will be o great importance to the company, as the 66th level i at a depth of 550 feet and is above the geologic horizon of the 7th level of the Keeley.

Cobalt—The [illegible] has [illegible] ahead 13 feet fro its recent discovery, and in addition has developed considerable tonnage of mill rock. The ore-shoot h been developed for a length of 60 feet, and show every indication of further extensions.

In the Southeast part of Coleman township, th Victory has decided to continue its shaft, and is askin for tenders to sink an additional 100 feet below th 450 foot level, at which depth it is expected the vein will be met.

The Coniagas expects to cut the vein for which it h been driving on the 1,200-foot level of the Beaver with the next two or three weeks. A successful issue to th development will be of considerable importance, n only to the Beaver and the Coniagas, but to the cam as a whole.

During the week ending November 16th, shipmen from Cobalt amounted of ten cars sent out by t Coniagas containing 114,780 pounds of ore, and one c by the O'Brien, containing 64,360 pounds.

Kirkland—Steady progress is being made on t branch railway into the Kirkland district, and it expected that trains will be run into Larder next su mer. This is much behind the preliminary estimat as construction has been delayed by bad weather and shortage of labor.

West Shining Tree—It is understood that the To pah Mining Company of Nevada will not take up option on the Westree property, in Shining Tree. Le difficulties have also occurred in connection with t organization on the Murray Magrigg land in t meantime, the company is unable to proceed furt with work on that property.

CALGARY REFINERY IN OPERATION

The Imperial Oil Company Limited has started firing at its Calgary plant, which has just b finished. In place of the 2,500 barrels daily outp which was originally planned the production is 4,0 barrels. About 250 skilled workmen are being gi permanent employment in the $2,500,000 refinery. crude oil is being brought from the Montana field across the border from Alberta.

BRITISH COLUMBIA

Soda Ash Plant in Operation.—Developments have occurred this year in connection with deposits of soda near Chasm on the Pacific Great Eastern Railway, owned by the Lilloet Soda Co., which merit notice. A new industry, states A. W. Davis, district mining engineer, may be in the making. A small plant for the production of soda ash was installed recently which has turned out very successfully. Raw soda has been shipped intermittently from this point for the manufacture of soap but for no other purpose. The large amounts of salts of various compositions occurring in the dry belt of the great central plateau of British Columbia present great possibilities and the installation of chemical plants, such as the one noted, is of special interest.

Cariboo Property in Litigation.—Extensive property holdings in the Cariboo District, standing in the name of the Lightning Creek Gold Gravels and Drainage Co. Ltd. are an issue in litigation before the Provincial Courts on the 21st November last. Application was made on behalf of the Company named and Charles H. Tnverzagt, New York, for an order compelling Joseph Carpenter Jr., of Wilmington, Delaware, to increase the amount of security advanced by him for the payment of defendants' costs in the event of his suit failing. Accordingly Carpenter is to be asked to add $1,000 to the $300 already put up for this purpose. Carpenter alleges mis-management of the Wingdam placer mining project. He seeks an accounting of receipts and moneys expended as well as damages against Tnverzagt. An order was made providing for the examination of Carpenter on discovery at Delaware.

Rossland Mines Shipping.—Rossland Mines now are reported to be making daily shipments to the Trail smelter, Consolidated Mining and Smelting Co. Properties that have been non-producers for years again are yielding ore. Consequently there are more men employed in the historic mining camp, business has materially improved, and the outlook is bright.

Silver Find Reported at Alice Arm. Specimens of high-grade silver ore have been taken from the Toric group of mineral claims, adjoining the Dolly Varden mine, in the Kitsault Valley section of Alice Arm district. Some of the samples have given returns on assay that, to say the least, are encouraging. Three veins are under development. One, it is said, starting a foot wide at the outcrop, widened to five feet when in a distance of about thirty feet. On the surface it can be traced for 400 feet. There has been considerable open cutting and stripping with satisfactory results. The ore is galena and argentite flaked with native silver. The owners are hopeful of having found the making of another Dolly Varden mine. The work of exploration and development will continue next season.

Tungsten Ore Reported near Prince George. A body of tungsten ore is reported to have been located on the property of the Granite Mining Company, Eaglet Mountain, near Prince George, northeastern British Columbia. An 800-foot tunnel is said to have tapped three veins of the mineral and a trial shipment is to be made to the Trail smelter.

Opposes Guarantee; Advocates Bounty.—The Board of Trade of Trail has gone on record as being opposed to the Provincial Government guaranteeing the bonds of a private corporation in connection with the initiation of an iron and steel industry. The Board, however, approves of the granting of a bounty on actual production.

Trail Ore Receipts. — Ore receipts at the Trail Smelter, Consolidated Mining & Smelting Co., for the week November 8 to 14 inclusive, totalled 8,972 tons, made up as follows:

	Tons
Alamo, Alamo	51
Company Mines	8,112
Emerald, Salmo	50
Knob Hill, Republic Wn.	137
Lone Pine, Republic Wn.	238
Quilp, Republic Wn.	71
Ruth, Sandon	36
Silversmith, Sandon	182
Van Roi, Silverton	95
	8,972

Usk.—The Federal Mining Co., is reported to have taken over a promising prospect on Gold Creek, near Usk on the Canadian National Railway. The construction of a road from Usk to the property and development on the claims is proposed when weather permits.

Encouragement for the Prospector. Dr. A. McKenzie Meldrum, Chancellor of Spokane University, addressing a Board of Trade meeting at Vancouver recently, pleaded for more encouragement and support for the prospector. Intelligent mining investment had made much more money than had ever been made in real estate. The indifference of citizens of the country toward mineral resources, and the lack of encouragement afforded prospectors and mining development in all its stages, were deplored. Most of the large business blocks in Spokane were the result of the earnings of mining enterprise. It was suggested that this was not true to any extent of Vancouver. It was a pity to see the prospector becoming an extinct species. The greatest of the world's mines had short lives as time goes. New properties must be discovered and there was no better prospecting ground in the world than British Columbia.

Immigrants Lack Employment.- Some forty or fifty men reached Nanaimo during the third week in November, having come from Great Britain, according to their account, as a result of glowing accounts of Western Canada and its possibilities as a [illegible]. Many of them are coal miners and so they headed for the chief coal mining centre of British Columbia. Unable to obtain work immediately, they sought the assistance of the Provincial Government. The representations [illegible] and their present condition are being made the subject of investigation.

A Municipal Venture. The city of Vancouver has decided to go into the coal business. The city pays $9.20 [illegible] and it is figured that this coal can be delivered at the [illegible] at $9.25 a short ton. This is a substantial reduction as compared to the retail prices of graded and screened as sold by the retail dealers. It is pointed out, however, that [illegible] can be supplied by [illegible] cannot be delivered.

ALBERTA

The British Petroleums Oil Well.—Oil has been struck by the British Petroleums Ltd., at a point in northern Alberta nine miles north of the town of Wainwright and in close proximity to Edmonton, the capital of the Province. Accounts of the occurrence indicate that, after the drill passed through an 18-foot sand stratum at a depth of something over 2,000 feet on Saturday, November 10th, baling showed distinct indications of oil. Baling was continued for three days and, on the following Tuesday, the flow was established. At noon on that day there were 1,535 feet of oil in the casing and at 3 p.m. on the same day it had increased to 1,750 feet. In the well is an 8¼ inch casing and running from it is a flow line of smaller dimensions. On the night of Tuesday the oil gushed from the flow line as high as the derrick and all valves were closed immediately. Drilling started last June but there were some delays, there having been six weeks of actual drilling with a 10-hour shift daily. The work was done by the Edmonton Gas & Development Co., under the supervision of E. H. Campbell, field manager, with D. O. Credille as head driller.

The headquarters of the British Petroleums Ltd. are at Vancouver. Newton W. Emmans, geologist and petroleum engineer, on returning from an inspection of the Fabyan-Wainwright field, said that undoubtedly the Wainwright well is the best that has yet been brought in, in the western Canadian field. The oil was found at the base of the Benton shale where it was not expected, plans having been made to drill to the Dakota formation. It is thought that greater production will be obtained in this field at greater depth. As it stands, however, it is the most promising that has been struck in this part of America, the Imperial Oil Co's well at Fort Norman having a capacity of 75 barrels a day while the wells in the Okotoks field are described as being more or less "freaks", gushing intermittently an oil that is almost a naphtha.

Naturally the event has caused excitement in Edmonton and other centres of northern Alberta. Officials of the Dominion Land Department at Wainwright found the entrance to their offices thronged when they came to open for business on the morning following the announcement. It was estimated that four thousand acres of land in the Wainwright district had been taken up by lease during the day. An excursion from Edmonton to the new well, which was arranged several days later, took hundreds of people to the scene. For their benefit the "gusher" was permitted to "gush" and newspaper correspondents wrote columns of "human interest" accounts of how oil shot above the ninety-foot derrick, plastering the latter with chocolate colored oil and covering the ground with pools of the precious liquid — demonstrating beyond cavil that northern Alberta has a real producer."

There are various estimates of the production possibilities of the well. At first it was placed at 100 barrels a day but subsequently that figure was doubled and it is maintained by some that 300 barrels a day will be found to be more nearly correct. The oil is lighter than that of Texas and certain districts of California and its gravity about 18 or 29 degrees Beaume. The pressure is about 500 pounds, according to Mr Campbell. This is considered about right to keep the oil flowing freely.

Mr. Stutchbury in Ontario.—Howard Stutchbury, coal commissioner for the Province of Alberta, has started East to make a lecturing tour of the Province of Ontario, his subject being the quality of the coal produced in Alberta and the advantages that may be expected to accrue to Ontario consumers through its use.

Alberta Coal Well Received.—The trial shipment of Province of Alberta coal to the Province of Ontario appears to have been successful in winning popularity for the western production in the eastern market. The Natural Resources Intelligence Service Department of the Interior, Ottawa, has issued figures showing that nearly 150 carloads were shipped of which London took 17, Guelph, 10; Toronto, 5; St. Thomas, 4; Ottawa and Hamilton, 3 each; Oshawa, Owen Sound, and Port Hope, two each. These figures include "reorders" which, it is stated, were "the rule."

NOVA SCOTIA

Commission Finishes Sittings.—The Royal Commission finished taking evidence in Sydney today when General Superintendent Bischoff appeared and gave his views on the period of agitation covering the February and the July strikes at the steel plant. The enquiry was most thorough and while the majority of the local public believe it was rather belated, yet the atmosphere has been cleared and many workmen have had an opportunity to air their grievances, both real and imaginary.

High Wages Today—Mr. F. W. Gray in his evidence pointed out that wages today are 36% higher than during the war and 11% higher than the war peak wages, because the cost of living was relatively lower. He presented a comparative statement of wages and cost of living to back up his assertions. A number of men contended that the cause of the trouble was due to small wages and the difficulty of getting their grievances before the officials. Quite a number of workmen expressed very favorable opinions of the General Works Committee plan and said that it would, if given a fair trial, work out to the best interests of employer and employee.

Non-Recognition of Union—The labor leaders blamed the Company for not recognizing the Union, while much of the evidence went to prove that the Union failed to control their members and that orders to refrain from the use of force in restraining men from working during the strike were more honored in the breach than in the observance.

Rioters Sentenced—One feature of the case which stood out prominently during the sittings of the Commission was the fact that some of those who raided the different departments of the steel plant to drive men from their work have been sentenced to several years in the penitentiary, their cases having been before the courts for some time.

Good Feeling in Wage Conference—Negotiations on a new wage agreement between the United Mine Workers of District No. 26 and the British Empire Steel Corporation have been opened up. We are not in a position to state the basis of agreement offered by either side, but we do know that the spirit animating all the representatives taking part in the discussions is much different from that shown in the last joint discussion. The offensive attitude of some of the labor

leaders has been dropped and a seriousness becoming to thenature of the case is being shown. The general opinion is that negotiations should be so conducted that good-will will be promoted; then, when the matter is settled, a spirit of harmony will pervade the colliery organizations and the whole community will profit by the understanding reached. There is no general feeling in favor of a strike among the workmen, for most of them realise that there has been far too much loss of time in the past three years through the rashness of their leaders. While all will gladly accept an increase in wages if freely granted, the majority of the workmen are ready to work on and wait for a more suitable season to enforce or press their demands.

Saner Leaders—The leaders themselves are fully alive to the fact that it is a mad policy to try to hold office by dangling large increases before the eyes of the workmen. Since ever the United Mine Workers union was organizd in Nova Scotia this has been done, and it was one long war dance, each leader trying to outdo the other before the eyes of the braves for the position of "Big Chief." But it led some over the edge of the precipice, and one into quiet and enforced seclusion; and although two or three did survive and get back on the executives, the rope still dangles on the brow of the cliff.

The Pruning Hook—One thing that the mine workers cannot fail to notice is the great amount of pruning being done by the Steel Corporation. Whether all of it is necessary or in the best interest of good business, is no part of this argument. The fact is that it is being done with the object of cutting down expenses and lowering the cost of production shows that an attempt is being made to put its coal and steel industry on a competitive basis. If, therefore, retrenchment is being made on such a large scale, it is reasonable to suppose that no general increase in the wage rates can be given at this time.

Too Many Datal Men—There is one feature which will be kept in sight by both parties in striving after results, that is, the balance of labor. No doubt it has been pointed out by both the expert American mining men and by President Lewis that the proportion of datal men to undercutters is far too large and the number of datal men should be largely reduced. Mr. Lewis in 1909 pointed this out. But it is one thing to see these things and another to change them and keep the collieries' outputs up. Conditions differ in different coal fields. Our American neighbors seem to be "favorites of fate" in this respect. We of the East are not caressed in pleasure's lap, and it is just as much the duty of labor leaders to consider the condition under which a coal seam can be mined as it is to consider the wages paid to those working the mines. If the conditions under which coal is mined are harder in Nova Scotia, let the International union recognize this and, out of their wide experience and their knowledge of mining and industrial conditions generally, step in and help to put the industry on a basis where it can not be be menaced continuously by competitors and thus caused to lead a precarious life.

Steel Plant Busy—All departments of the Sydney steel plant, the rail mill excepted, are working steadily, and there is more real contentment among the workers than has been for the past three years. Rail orders are scarce, however, and now that the heavy "H" beams for the new colliery have all been finished, the mill is idle. The rail mill workers are employed on the smaller mills.

A large exhibit of steel products has been prepared and labelled for the British Empire Exhibition to be held in London next year.

Coke for Domestic Use—Satisfactory progress is being made in the sale of Sydney coke. The sales so far have been largely confined to the Maritime Provinces. No difficulty has been experienced in getting dealers to handle the product and these could sell more than they can get. With the new battery of ovens going, there will be a larger supply, which should come near meeting the demand. It is understood that coke will be sent to Quebec province shortly and arrangements are now being made to handle it there.

As the domestic use calls for different sizes, coke from the new battery will be crushed and assorted. So far only coke breeze could be spared, but the provision of lump coke will no doubt pave the way for a steady trade in the near future.

SAFETY FIRST COMPETITION

It is announced in the **Granby News of Anyox** that the prize offered by the Granby Company for the best definition of "What Safety First Means to Me," has been awarded to T. M. McAuliffe of the Mine. It is given below, as well as one which came a close second sent in by Mr. L. Waide, also of the Mine. While there were a number of good efforts in this competition from the Beach, the two published below have been judged the best.

What Safety First Means to Me
By T. M. McAuliffe

It is the natural law of Self Preservation.
It is the Antithesis of Ennui and Bravado.
It forms a Stepping Stone to Remunerative Effi ciency.
It Visualizes the Fact that an Injured, Careless Monetary Sympathy.
Worker seldom deserves, and rarely receives, Moral or Collectively it Emphasises the Continuity of Employment.

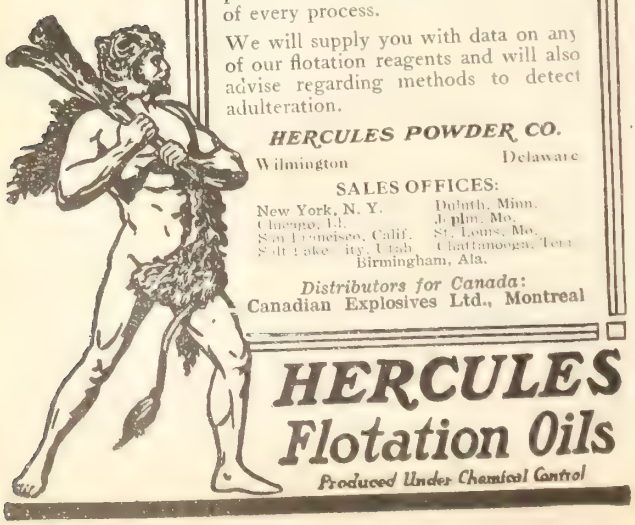
What Safety First Means to Me
By L. Waide

I appreciate and Value every Little Wonder that Nature gives me:
To derive Full Benefits of Eyes, Ears, Mouth, Hands. Feet, etc, and keep them Sound and Intact.
Safety First Industry distinguishes between—Speed (Fast work Accompanied with Thought and Con centration) and Haste (Reckless, fast work with a Minimum amount of Thought.

LEACHING OF CAVED MINE AREAS

At copper mines, many old dumps, stope fillings, and similar accumulations of low-grade copper-bearing material, formerly regarded as waste, may now, under proper conditions, be leached in place, states the United States Bureau of Mines. A large copper company is now leaching its old caved areas successfully. Its officials have been given all the encouragement and assistance the Bureau of Mines could fittingly render; they have become convinced of the necessity for close technical control of their solutions to prevent loss, and are giving the Bureau facilities for studying the beginning of what appears to be an important means of saving low-grade values.

Discussing the work of the British Imperial Conference, this week's *European Commercial* states: "There are, at the present time, advocates of a completely self-contained British Empire. They would like to see a detailed system of Imperial preference set up with the ultimate object of securing the exclusive use or British products in the Dominions and vice versa. For ourselves, we look at the matter mainly from the European point of view. The British Empire cannot absorb its own output, and, as this is principally designed to appeal o purchasers on a high plane of civilization, the markets of Europe must be taken into consideration in an ever increasing degree. Nor can the flow of goods be in one direction only, and if Europe is to purchase from Britain and the British Empire, these latter must purchase European products in return. The restoration of Europe is a concern of the most vital importance not only to Britain, but also to the Dominions."



We Meet Your Specifications
We are prepared to furnish you with a standard line of exact flotation reagents. If you desire, our technical staff will gladly co-operate with you to determine the particular flotation oil which will best meet your requirements.
As soon as the specifications have been established, we will guarantee strict adherence to them and practical uniformity in every shipment. We can do this because Hercules Pine Oils are produced under rigid chemical control of every process.
We will supply you with data on any of our flotation reagents and will also advise regarding methods to detect adulteration.

MINES BRANCH

Recent Publications

Talc and Soapstone in Canada, by H. S. Spence.

Titanium, by A. H. A. Robinson.

Summary Report of Investigations made by the Mines Branch during the calendar year ending Dec. 31, 1921.

Phosphate in Canada, by H. S. Spence.

The Preparation, Transportation and Combustion of Powdered Coal, by John Blizard.

Road Materials along the St. Lawrence River, from Quebec Boundary to Cardinal, Ont., by R. H. Picher.

Barium and Strontium in Canada, by H. S Spence.

The Coal-fields and Coal Industry of Eastern Canada, by F. W. Gray.

Analyses of Canadian Fuels. Part I to V, by E. Stansfield, M. Sc., and J. H. H. Nicholls, M. Sc.

Graphite, by H. S. Spence.

Gas Producer Trials with Alberta Coals, by J. Blizard and E. S. Malloch.

The Mines Branch maintains the following laboratories in which investigations are made with a view to assisting in the developing of the general mining industry of Canada:—

Fuel Testing Laboratory.—Testing value of Canadian fuels for steam raising and production of power gas; analyses, and other chemical and physical examinations of solid, liquid and gaseous fuels are also made.

Ore-Dressing Laboratory.—Testing of Canadian ores and minerals, to ascertain most economical methods of treatment.

Chemical Laboratory — Analyzing and assaying of all mineral substances and their manufactured products. Copies of schedules of fees, which are slightly in excess of those charged by private practitioners, may be had on application.

Ceramic Laboratory.—Equipment is such that complete physical tests on clays and shales of the Dominion can be made, to determine their value from an economic standpoint.

Structural Materials Laboratory.—Experimental work on sands, cements and limes is also undertaken.

Applications for reports and particulars relative to having investigations made in the several laboratories should be addressed to The Director, Mines Branch, Department of Mines, Ottawa.

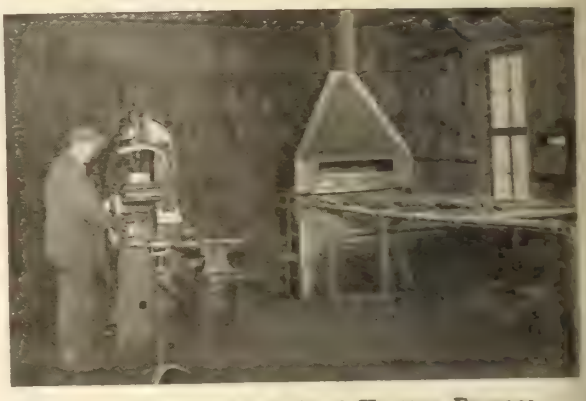
"Sullivanize" Your Drill Steel



Sullivan Sharpeners and Steel Heating Furnace

DON'T handicap your rock drills or delay your runners by using steel that is improperly heat-treated, badly formed or poorly sharpened. Train your Blacksmith to put as much footage as possible into each steel he on the job.

Sullivan Furnaces and Sharpeners Provide Drill Steel Quality Insurance

The *Sullivan oil or gas Furnace* heats the steel gradually, evenly, while electrical devices prevent overheating or burning, and indicate, also if the steel is not hot enough for working or tempering.

The hammer-forging action of the Sullivan Sharpener refines the grain of the metal, and with each repeated sharpening renders it tougher, less liable to wear or breakage. Sullivan-sharpened bits are made to exact shape and gauge by tool steel dies and dollies. They "follow" accurately in the drill hole.

With the Sullivan gauging device, genuine double taper bits are quickly and correctly formed, providing increased drilling speed.

Sullivan Furnaces and Sharpeners insure that each steel is of uniform hardness, of exact shape, that the steel quality you paid is preserved and that you will obtain the maximum feet of hole from each steel.

Sharpeners, Bulletin 672-E

Furnaces, Bulletin 674-A

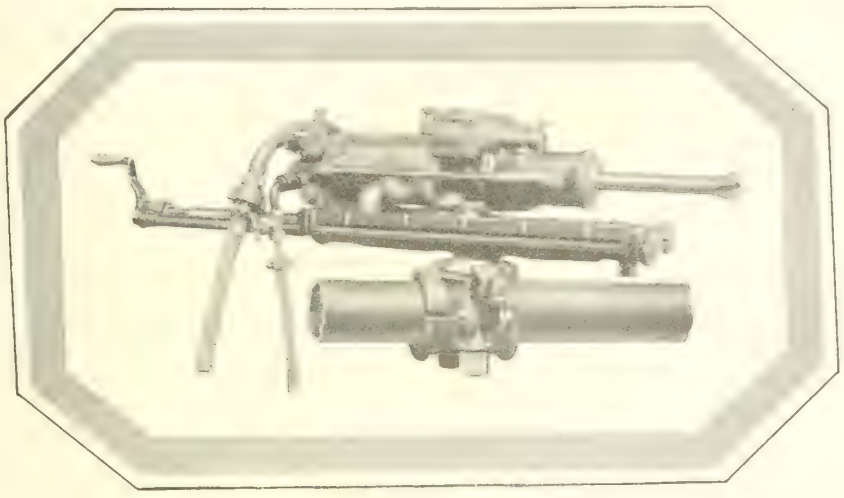
"The Waugh Way Wins"



A Tri-State Tribute

AGAIN this year, for the third successive time, the Waugh Model 21 Turbro has emerged triumphant from the Tri-State rock-drilling contest a grilling ordeal for both men and machines, which is also recognized everywhere as a sound criterion of drifting-drill merit.

THIS year the contest was held at Miami, Oklahoma, and as usual, the Model 21 Turbro, taken at random from a branch stock, won first, second and third places against all competitors.

THAT these repeated victories are not the result of mere coincidence, but of sheer merit, is an obvious fact. Ask any drill-runner in the Tri-State District. He will tell you that

"The Waugh Way Wins"

We'll be glad to send you a copy of the Turbro booklet. Ask the nearest Waugh branch office for one today.

The Higher Cost of the Lower Price

For every shutdown of its crushing plant it costs the big mine $8.00 a minute. Another large operator figures his costs for lost time somewhat higher.

Probably your own records would reveal similarly alarming figures.

Telsmith Primary Breakers and Reduction Crushers cost more than many competing types but in most cases they do better work, sometimes indeed performing tasks that other crushers could not attempt.

Records of scores of mines show that Telsmith crushers not only have a larger output than many other machines of similar size but are also stronger and lighter than machines which depend on mere bulk for strength.

Telsmith crushers provide effective insurance against suspended production and operating deficits due to crusher troubles so that in the end they prove far cheaper than machines of lower first cost.

Our new bulletin just off the press explains the advantages of Telsmith Crushers in detail.

O.W. Ludwig, *Plant Superintendent of the Raymond Lead Co., Chicago, says:*

"Thirteen years of service without a repair is our experience with two 100 H.P. and ten 20 H.P. Morse Silent Chain Drives.

"When we moved into our present plant thirteen years ago, we installed the present Morse equipment of silent chains for our two lead mills and ten hydraulic pumps. We had always previously used leather belts, but not without considerable trouble. For instance, if the operator was not careful — and gave the motors too great a load, the leather belt would slip and in some cases burn out. While with the Morse Chain Drive we overload them at times up to 15 H.P. without the slightest trouble.

"When we used leather belts on the hydraulic pumps, if a pump packing suddenly gave way, the water would squirt all over the pump as well as adjoining pumps, causing the leather belts to get wet. This often necessitated a shut-down on 3 to 4 pumps to dry out each belt, thus causing a loss of time by the men, which resulted many times in paying overtime to catch up on the work. Of course, with our Morse Chain Drive we have no such trouble—this positive drive prevents slippage and is not affected by water.

"Leather belts lasted us 2 to 3 years at the most, while our Morse Chain Drives have already lasted 3 to 4 times that long and seem good for many more years. So Morse Drives have cut our expense materially, speeded up production, cut out overtime wages and saved floor space, for they operate on shorter centers."

Ontario's Minerals

PROVINCE OF ONTARIO

Hon. CHARLES. McCREA, Minister. DEPARTMENT OF MINES *Thos. W. Gibson*

Mineral Areas

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favourable for the occurrence of minerals 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver veins of Cobalt, Gowganda and South Lorrain occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

Economic Minerals

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario: — actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluorspar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, Portland cement, brick and tile, meet every demand.

Mineral Production

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1922 to be worth $62,202,169, of which the metallic production was $38,190,711.

The following figures show the growth of Ontario's mineral industry by five-year periods since 1891 when a Bureau of Mines was first established.

Year.	Value.	Year.	Value.
1891	$4,705,672	1911	$41,976,797
1896	5,235,003	1916	65,303,822
1901	11,831,086	1918 (Maximum war output)	80,308,972
1906	22,388,383	1921	48,128,387
	Dividends.		

Dividends and bonuses paid to the end of 1922 amounted to $28,096,699 for gold mining companies, and $86,238,185 for silver mining companies or a total of $114,334,884.

Mining Regulations

A miner's license costs $5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of $2.50 or $3.00 per acre, depending on location in unsurveyed or surveyed territory.

Assay Office

The Provincial Assays Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

Adding Impetus To The Development of Mining

The development of Canada's enormous natural resources will affect her whole future. Her vast mineral wealth, as yet practically untouched, is to-day attracting world-wide interest from far-seeing investors.

It is appropriate that the Imperial Bank, whose policy has ever been to concentrate exclusively on Canadian affairs, should be powerfully furthering that interest. This Bank, by placing branches at strategic points throughout the mining districts, has materially aided the whole industry.

Those who contemplate becoming connected in any capacity with mining would be well advised to take advantage of this Bank's facilities.

IMPERIAL BANK OF CANADA

:-: EDITORIAL :-:

TAX RATE SHOULD BE FIXED

The government at Quebec has not yet announced e method or the rate of taxation it will impose upon e prospective gold mines of the province. That gold ning, along with all other industrial undertakings the province, must bear its share of the burden of xation, one must take for granted; but those who ve invested in the development of gold prospects d who expect to expend larger and larger sums to velop mines and build mills, as occasion may warnt, are faced with an undetermined liability. They do not know what share of their output or of their ofits the provincial government will demand.

This is one of the problems the government at Que- will have to face eventually; and the sooner it nfers with all concerned and reaches a decision, the tter will all be pleased. It requires a very substanal investment to bring a new gold mine to the point production, even if exploration should have the st favourable outcome possible. Those who will t up this money will want to know, naturally, what eir liability is in the way of taxes. It is quite posble that the occasion for this investment will arise thin the next six months. It is, therefore, incumnt upon those responsible at Quebec to "get busy."

There is one point that seems to warrant mention w. The natural tendency of those who formulate x regulations is to impose a flat rate on production. his is the simplest and most direct way of comput- g and collecting a tax; but it is by no means the st. It has been demonstrated by the history of gold ning in Ontario, for instance, that a flat tax or yalty on production hung like a dead weight round e neck of the industry. The present graduated tax profits is more equitable, and has aided numerous ld mines that were originally of doubtful value to ach a profitable. and taxable, position.

DEPARTMENT OF MINES REPORT

The annual report of the Department of Mines, tawa, for the fiscal year ending March 31st, 1923, s just been issued. It is a document whose imrtance is seldom matched by the publicity it reives; therefore we shall give it some attention here. In his brief report, the Deputy Minister, Dr. Charles msell, touches on the principal problems the Dertment has undertaken to investigate. He first ms up the situation thus:

"The mineral resources of Canada are among its greatest natural assets, and, owing to our natural climatic conditions and the relatively limited area of the country capable of agricultural development, the mining industry must necessarily occupy a relatively larger place in our economic development than in those countries of the world more fortunately endowed with respect to climate. Mining is not affected by climate and can be carried on irrespective of it. The importance of this industry is indicated by the growing increase in the annual production of minerals per capita, which has risen during thirty-five years from $2.23 to $26.40 a head of population. This curve of production is increasing from year to year until it should ultimately exceed that of any country in the world. The two essentials to increased mineral production are markets and capital. Under present conditions the former is the more important and is necessary to encourage the latter. Owing, however, to the conditions mentioned above, namely adverse tariffs or the conditions of exchange, foreign markets are today difficult for us to enter. It is urgently necessary, therefore, that we should develop home markets by the establishment of industries complementary to the mining industry, so that the products of our mines may be utilized for manufacture into finished articles. A study of our mineral trade balance will show several instances where the raw material for a manufactured article is produced in this country, but is shipped outside for manufacture and is then sold back to us at many times the value of the material in it. The securing of capital for the development of these complementary industries appears to be more in the general interests of the country than capital for the production of raw material, and until those complementary industries are established in our own country the production from the mine will not increase to a stage bearing a proper relation to what we believe to be our potential resources."

Following up his own suggestion, Dr. Camsell mentions the work of the Dominion Fuel Board in providing Canadian fuel for Canada, and that of the Mines Branch in investigating and aiding the establishment of native industries using our own minerals.

In reporting for the Geological Survey, the Director Dr. W. H. Collins, stresses the need for accurate maps as does also Mr. W. H. Boyd, Chief Topographical [illegible] the Survey. Mr. Boyd [illegible]

to pre-war strength and the work is progressing satisfactorily. While the geological field work has the economic end as its chief object, the purely scientific aspects are by no means neglected.

In his report for the Mines Branch, Dr. John McLeish, Director, points out that, while our mineral production for 1922 reached the respectable total of $183,000,000 and our exports of mineral products (including those partly or completely manufactured) was $115,000,000, our imports of minerals were $282,000,000. His Branch is particularly charged with the responsibility of reducing this huge total of imported minerals, much of which is available at home if only we would take the pains to use it. To help the public to investigate and use our own minerals there is available the aid of the Branch's five divisions, namely the Division of Mineral Resources, which reports upon mineral resources in general; the Ore Dressing and Metallurgical Division, which investigates methods of treatment; the Fuel Testing Division; the Ceramics and Road Materials Division; and the Chemical Division, concerned chiefly with analysis.

The Department of Mines includes also the Explosives Division, in charge of Lt.-Col. G. Ogilvie, which licenses and inspects all explosives factories in the Dominion, of which there are now sixteen. The Dominion of Canada Assay Office in Vancouver is another branch of the Department of Mines that is seldom noticed except by those directly concerned. During 1922 it received gold and silver of a total value of over two million dollars.

A USELESS ROAD

The plans for a first-class winter road to the goldfield of northwestern Quebec have gone agley. On November 16th we announced the fact that Hon. J. E. Perrault had authorized the construction of a road from Angliers, the present terminus of the Canadian Pacific Railway line on the Quinze river, northward to the gold belt, by an all-land route. Either we were mis-informed at that time as to the route, or it has been changed subsequently. A contract has been let for cutting the road from Angliers to the Lonely river by land, whence it is the intention to put the road on Lake Opasatika for the remaining distance of sixteen miles to its northern end, where it touches the existing east and west road from Dane to Rouyn township.

At present supplies for the camps in Rouyn and Boischatel townships are being brought in by sleigh over the road from Dane on the T. & N. O. Railway, a total distance of close on sixty miles. The portion of the road from Dane to Larder is good; but from Larder to Lake Opasatika and Lake Fortune it is far from good. We climbed up and slithered down its hills recently, and have a wholesome respect for them. The load a team can draw over this road, even on sleighs, is ridiculously small, and the expense of bringing in supplies is correspondingly high.

On the southern route from Angliers there are no hills to contend with, and the provision of a good winter road would lessen materially the expense of supplies to the operators on the gold belt. Four shafts are to be sunk during the winter and a number of diamond-drills kept in operation. In addition mining machinery and a stock of supplies for the ensuing summer will be brought in. The expense of hauling all this material will be a considerable proportion of the total expense, and should be kept at a minimum.

If the road from the south runs the length of Lake Opasatika on the ice, it is doubtful whether the mine operators will be able to use it at all. A road on a large lake such as this is notoriously hard to keep open and it is impassable with heavy loads a good deal of the time on account of the slush that forms as the ice sinks with the weight of snow. The three mining companies operating on the gold belt are already using the road to Dane to bring in supplies, and it is more than likely they will continue to use it in preference to a road that runs the length of Lake Opasatika.

We refer to this point at some length because we were among those that urged the building of this winter road in the first place, and feel in some measure responsible for it. If its location remains botched, as at present, it seems possible that it will not be used and that the investment will be wasted. There is still time to save the situation by continuing the road sixteen miles by land northward from Lonely river to intersect the present road in Boischatel township. The cost of this would be in the neighborhood of $2,000—a bagatelle compared with the saving in freighting expenses that would result.

WOLF! WOLF!

The terrible wolves of our north country constitute an ever recurrent theme for newspaper writers as winter approaches. Probably Grimm's fairy tales and some ancient and honourable nursery rhymes are responsible, in the main, for these stories. The memories of Red Riding Hood and the big teeth that gobbled up the poor, old grandmother remain vivid in the imagination, and completely exclude the repeated statements of the human denizens of the north woods that wolves are a comparative rarity, and that dogs are more dangerous than their untamed relatives.

The wolf in northern Canada is one of the rarest of animals to be seen, and is the most fearful of man. Infrequently wolves are shot by skilled hunters, and sometimes they are trapped, though it requires more than the ability of the average trapper to deceive this wary animal. Often one hears the wolves howling, especially when in hot chase of a deer, their chief quarry; and sometimes on a still night they set up a brief chorus. But even the sound of the wolves is usually from a distance that is perfectly safe for them, and comforting to the wolf-shy greenhorn in the woods.

COMPANY MEMBERSHIP

Thirty representative members of the Institute have submitted an amendment to the by-laws, as announced in the December issue of the *Bulletin*. They propose that bona fide mining or metallurgical companies be authorized as members of the Institute, with the full powers and privileges of a private member, and that they be represented for voting by one who is already a member or associate member. The annual fee for company membership is to be $50.

This is a direct and straightforward bid for financial support from mining companies that feel able and inclined to contribute a modest annual sum to the Institute's coffers. The Institute requires urgently an augmented income, and the present proposal appears to provide a reasonable way of getting it. On first thought, such a request from the companies for an annual contribution (for it amounts to that) seems hardly in keeping with the Institute's dignity; but on reflection this appears a shallow view of the case. The Institute's stated reason for existence is to forward the interests of the mineral industry as a whole. These interests coincide, in most cases, with those of the companies whose operations constitute the industry. The companies have at present no official representation in the Institute, such as the Geological Survey and the Mines Branch at Ottawa have now. Nor have they the means at present of giving financial support to the organization that is fighting their battles and promoting the progress of technical efficiency. The stated and moderate annual dues proposed overcome the objection we have made on former occasions to gifts of money to the Institute's general fund.

The *Canadian Mining Journal* approves heartily the proposed amendment. Its adoption is likely to result in a moderate increase in the Institute's revenue, while it will leave unimpaired its prestige and usefulness.

CUSTOMS OFFICER IN NEW YORK

The government at Ottawa has at last announced its intention of stationing a Canadian customs officer at the port of New York to supervise shipments of Canadian goods from east to west of Canada, or vice versa, via the Panama canal. On several occasions during recent months we have pointed to the anomalous condition that exists at present, when only full cargoes between Canadian ports are immune from customs duties, while consignments on a vessel that discharges or takes on cargo at New York, the principal port of call en route, are liable to the full duties on foreign goods. The simple expedient of appointing a customs officer to supervise the loading and unloading of these vessels in New York, with a view to protecting the legitimate customs revenue, will solve the whole problem. The government has acted tardily but wisely.

TWO MORE GOLD MILLS OPERATING

All interested in Ontario's gold mining will watch with interest the progress of the new mills of Vipond and Night Hawk Peninsular, now tuning up for steady production. The Vipond mill already has a small production to its credit under a former management which failed to develop sufficient pay ore to keep it running. The present company has turned failure into success by judicious underground exploration, and has remodelled its 150-ton mill for the steady grind ahead of it. The Night Hawk Peninsular management has reported to the share-holders that there is plenty of ore in reserve to warrant its mill of 200 tons daily capacity, and that the grade is such as to afford a handsome operating profit. These two new producers will add a sum approximating $4,000 a day, or $1,250,000 a year, to the province's output of gold.

A SUBSTITUTE FOR THE LABOUR UNION

It is not many months since the Industrial Council plan proposed by Mr. Bischoff for the steel works in Sydney, Nova Scotia, was hooted and booed by the steel workers. At that time insurrection was in the air, and sane thought was a rarety. Now that the air has been cleared by the strike and its settlement, the Bischoff plan has been adopted with a marked measure of success.

With some unimportant exceptions, all are pleased with the new joint control of industrial relations. The old system of absolute rule by foremen, superintendents and managers is a relic of mediaeval times and is quite out of tune with democratic ideals. The modern system of joint control and combined responsibility is not only suited to the ideals of our times, but has been proved by practice to be entirely workable, if applied with reason.

The British Empire Steel Corporation have inaugurated in their steel works a plan of coöperation with their workmen that may well prove to provide all the genuine advantages of the labour union without including the features that have brought it into such serious disrepute.

COAL OUTPUT CLIMBING IN NOVA SCOTIA

Coal production in Nova Scotia this year will be at least 6,000,000 tons, according to the Hon. E. H. Armstrong, Premier of Nova Scotia and Minister of Mines for the province. As the total production last year was [illegible] tons, the increase this year will be the equivalent of [illegible] million tons. The collieries are in good condition and preparations are in progress for the opening of new mines.

DAILY OUTPUT OF RAND

The average daily output of gold from the Rand mines during September was [illegible] ounces, against [illegible] ounces a day in August. [illegible] were employed in the mines during September.

Recent Mining Developments in the Mayo District, Yukon*

By W. E. COCKFIELD

Last year the *Journal* published an account by the writer of the silver-lead discoveries of the Mayo district, Yukon. This district was revisited by the writer last summer and most interesting developments were seen.

Keno hill, which is situated 40 miles northeast of Mayo, is at present the most important mining centre in Mayo district, which district lies on the eastern boundary of Yukon and may be roughly defined as the watershed of upper Stewart river. The Stewart, one of the main tributaries of Yukon river, joins it 72 miles above Dawson. Mayo is situated 180 miles above the mouth of the Stewart river.

Communications

During the summer the White Pass and Yukon Company maintain a regular passenger and freight service on Stewart river, in connection with the boats on Yukon river. In winter passengers may reach Mayo by means of the mail stage which connects at Minto on Yukon river with the overland mail from Whitehorse to Dawson. Telegraphic communication between Mayo and Dawson has recently been established, thus furnishing communication between Mayo and outside points. Good roads have been constructed in Mayo district by the Territorial government, and a telephone line between Mayo and the mines has been installed by private enterprise.

Hitherto practically all hauling between the mines and Mayo has been done by horse-drawn sleds in winter. Last winter, however, the Treadwell Yukon Company, Ltd., introduced caterpillar tractors. These hauled the bulk of the ore shipped by this company and were entirely successful in operation, reducing the cost of haulage by approximately 50 per cent. As the cost of landing ore to Mayo previously represented nearly half the cost of shipping from the mines to the smelters, this reduction is quite substantial.

Production

The estimated production of Keno hill from 1920 to the spring of 1923 is 14,200 tons, having a total content of 2,890,000 ounces of silver valued at $1,900,000 and 14,300,000 lbs. of lead valued at $665,000. The production during the winter of 1922-23 was 61 per cent. of this total. For the coming winter a production of between 8,000 and 9,000 tons is expected.

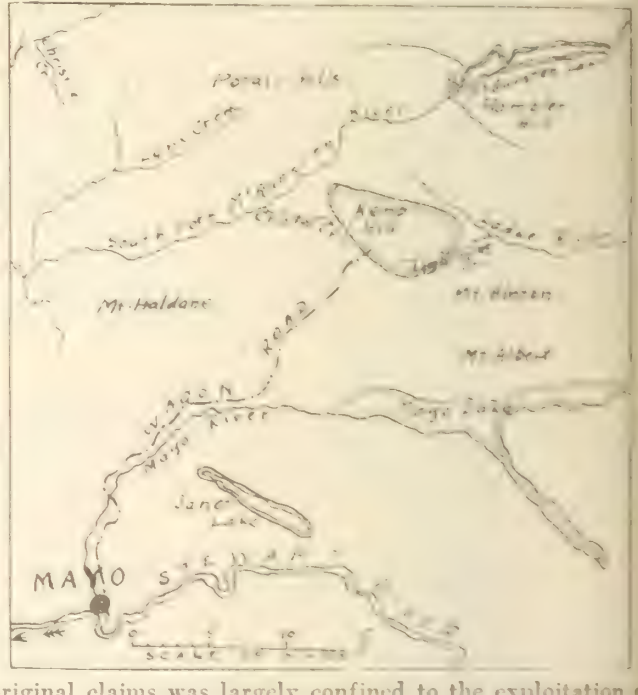
General Geology

The district is underlain by quartzites, quartz-mica schists, mica schists and graphite schists presumed to be pre-Cambrian in age. Intrusive into these schists are dykes, stills and laccoliths of greenstone which is also sheared. Dykes of quartz porphyry and granite porphyry cut both of these formations. These dykes are believed to be contemporaneous with a granite intrusive mass lying to the east.

The ore-deposits are mostly fissure veins or fault fissures filled with mineral. Two systems of mineral fissures have been recognized. The earlier has a general trend of north 30 to 40 degrees east and at the time of formation was mineralized with quartz and arsenopyrite. These veins probably served as the main circulation channels for the solutions during the mineralization of the second set of fractures and consequently contain some valuable deposits. The later series of veins make an angle of 70 to 80 degrees with the earlier series. The minerals of the second stage are chiefly galena, sphalerite, freibergite and siderite, with a little pyrite, calcite and barite. A third fracturing took place subsequent to the deposition of the ore-bodies, cutting some of the deposits into a series of fault blocks. Some of the veins, however, are quite undisturbed. This fracturing was accompanied by the deposition of quartz. In some places a slight secondary enrichment represented by native silver and ruby silver has taken place, but the effects of this are extremely localized.

Keno Hill, Ltd.

The original claims were staked close to the summit of Keno hill, and were bonded to the Yukon Gold Company, which later formed a subsidiary company, Keno Hill Ltd., to operate its claims on the hill. Other promising claims were also prospected by this company. The work on the original claims was largely confined to the exploitation of veins belonging to the second series as outlined above. These veins contained small ore-shoots of clean sulphides but the shoots as a rule were small. The bulk of the ore shipped came from vein No. 9, where the workings were carried to a depth of 400 feet; but below the second level (250 feet) the ore became disseminated, requiring concentration before shipment. Approximately 8,000 tons of shipping ore were extracted from this ore-shoot, and development work was suspended in order to open up the Sadie-Friendship vein on the western slope of the hill where the deposit gives more assurance of permanency. The possibilities of other ore-shoots in No. 9 vein have not been exhausted.



The Sadie-Friendship and Treadwell vein on the western slope of Keno Hill represents the most important addition to the Keno Hill camp since the original discovery, and gives promise of far surpassing the latter in produc

* Published with the permission of the Director, Geological Survey, Ottawa.

tivity. Discovered by accident in 1921, the vein has already been developed to such an extent that 4,300 tons of ore have been shipped. This deposit differs from most of the others on Keno hill in that it is a zone rather than a fissure vein. This zone follows closely a line of weakness represented by an older quartz-arsenopyrite vein, and has been found at points on the Sadie, Friendship, Bluestone, Ladue, and Lansing claims, and further outcrops possibly representing the same deposit occur on the Lake group to the north and east of the Lansing claim. As the surface is everywhere covered with tundra and as the vein is faulted considerably, the full extent of the deposit will not be known for some time.

The mineral zone is from 10 to 40 feet thick. The mineralization consists of galena, sphalerite, freibergite, siderite, calcite, barite, ruby silver and native silver. The clean sulphides do not occur as plentifully as in the veins on top of the hill, but by means of hand sorting, shipments of considerable size have been made. Plans for concentrating plants are now being considered and it is believed that such plants will lessen to some extent the cost of mining, as the whole deposit can then be mined.

Keno Hill, Ltd. has sunk three prospecting shafts on the Sadie and Friendship claims, and a short level was driven close to the surface from which 360 tons of ore were extracted. The property was not, however, adequately equipped with pumps and the workings filled with water and caved. With the closing of the properties on the top of the hill, however, power from the steam plant on Duncan creek has become available and a vertical shaft 200 feet deep is being sunk, with crosscuts to the vein at 70, 135 and 200 feet.

Treadwell Yukon

Treadwell Yukon Company, Ltd., has sunk two inclines of 280 and 175 feet on the Ladue claim. Levels connecting these have been driven at 50, 90, and 160 feet and from No. 1 shaft the 300-foot level is being driven in both directions along the vein. A drainage tunnel 3,000 feet long is also being driven to tap the vein at a depth of 500 feet. Recent reports state that this tunnel has already been driven 1,200 feet. This property is completely equipped with compressors, hoists and pumps.

Individual miners are also prospecting their claims, and a number of promising veins have been uncovered. During the winter of 1922-23 approximately 140 tons were shipped by individual claim owners, the Shamrock group situated near the original holdings of Keno Hill Ltd., and the Rambler group on the northern slope of Keno Hill being the chief producers. Further shipments from these sources are expected.

Other Occurrences

Veins similar to those on Keno hill have been found on Sourdough hill, lying to the south of Keno hill and on Galena hill, lying between Keno hill and the old Silver King mine, the first producer of high-grade silver-lead ore in the Mayo district. It is expected that in time further discoveries will be made. The country is difficult to prospect owing to the superficial deposits, which are largely frozen and require much work for their removal. This fact, coupled with the remoteness of the district, will tend to retard development.

A new and promising discovery of tinstone is reported from the Marranboy district in northern Australia.

A new occurrence of the banket reef, as yet of unproved value, has been found near the Wilge river, east of Pretoria, South Africa.

CONSOLIDATED CONTROL OF TOPOGRAPHICAL MAPPING IN OTTAWA

In every country surveys and maps are a necessity and this is particularly true of Canada with her great areas of undeveloped land. Three federal departments are, and have been for a number of years, engaged in making topographical surveys with three different objects in view. The Dominion Government, realizing the need of co-ordinating this work in order to secure the greatest measure of efficiency and economy, formed in 1922 the Board of Topographical Surveys and Maps.

The three departments and their fields of operations are as follows: the Department of National Defence has in mind the making of maps for militia purposes: it began the surveys for the series generally known as the "Militia Maps" in 1903. This series now covers approximately 40,000 square miles, mostly in the provinces of Ontario and Quebec. The Geological Survey of the Department of Mines has in view the use of maps for geological purposes, and commenced making topographical surveys in 1909; they have covered probably 35,000 square miles throughout various parts of the Dominion. The Topographical Survey of the Department of the Interior has in view maps for general purposes. In 1887 they commenced the photo-topographic survey of the Rocky mountains, which has been continued with interruptions up to the present time This survey now covers about 13,000 square miles and is confined, for the most part, to Dominion parks and forest reserves. For many years the Topographical Survey has issued the three-mile sectional sheets which cover a large part of Dominion lands in the western provinces. In 1919 it was decided to add complete topographical information to this series and up to the present time roughly 90,000 square miles have been surveyed.

By the Order in Council creating the Board of Topographical Surveys and Maps it is given authority to consider and advise upon all questions that may arise in relation to topographical surveys, the compilation of new maps, the modes of projection, the selection, unification, and improvement of scales and conventional signs, the representation of relief, the use of colours, and other geographical subjects. By means of the powers thus given it, the Board is bringing about a correlation of the work of these different organizations so that when any work is undertaken by one of them the work and needs of the others are fully considered.

The members of the Board are: Dr. Deville (chairman) and Mr. T. Shanks, of the Department of the Interior; Dr. W. H. Collins and Mr. W. H. Boyd, of the Department of Mines; and Colonel S. H. Osler and Major J. B. Cochrane, of the Department of National Defence.- Natural Resources (Ottawa.)

NOVA SCOTIA COAL SHIPMENTS TO ST. LAWRENCE PORTS

The [illegible] of the season have been shipped from the coal mines of Nova Scotia to St. Lawrence ports. The total [illegible] to the St. Lawrence ports [illegible] 1,100,000 tons. This is 84,000 tons in advance of last year, but is a smaller amount than was anticipated early in the season. The strike last summer caused many buyers to [illegible] from Nova Scotia to the United States.

Empire Resources in Oil

A Plea for the Commercial Exploitation of Torbanite

By E. H. CUNNINGHAM CRAIG, in "United Empire"

It is told of Pitt that, rising on one occasion in the House of Commons, he commenced his speech with the words "Sugar, Mr. Speaker"; at which some members were so ill-advised as to laugh. Whereupon, Pitt turned upon them in anger, and, raising his voice, reiterated "Sugar, sugar, sugar: who will dare to laugh at sugar now?" Those were the days when our West Indian sugar resources were a priceless asset, and before we had sacrificed our Colonial sugar trade to a craze for cheapness and an inferior product, the beet sugar of our Continental neighbours and rivals. To-day, oil in all its forms is of equal importance, not only to the Kingdom, but also to the Empire as a whole; and it is time, and more than time, that some statesman with as powerful a voice should rise in his place and begin with "Oil, Mr. Speaker."

Limited Empire Resources

Everyone now admits the importance of petroleum supplies; we have been told that "the War was won on oil"; but alas, it was only to a very small extent British oil. The world will always consume as much petroleum as can be supplied to it. Such temporary over-production as is taking place in the U.S.A. at the present moment only stimulates consumption, and brings the day when we shall want more than we can get so much the nearer. With a demand whose capacity for growth may, for all practical purposes, be regarded as unlimited, and with resources which, in spite of, or rather by very reason of, the development of new fields in Venezuela, Colombia, and elsewhere, are diminishing, surely it is obvious that, sooner or later—and it may be much sooner than is anticipated by many of our commercial magnates—a shortage is inevitable. And still, though the danger is evident, a policy of drift is tolerated, if not even encouraged.

During the War a golden opportunity was lost when no vigorous steps were taken to develop to the utmost our Imperial resources in sugar, with the result that the sugar market is now dominated by the price of sugar in Cuba, instead of in Hamburg as before the War, a change that certainly is little improvement from a British point of view.

In petroleum affairs a similar short-sighted policy was followed and another glorious opportunity lost. It is only by developing Imperial resources that the British Commonwealth of nations can regain and increase its ascendancy. But our Government delayed till far too late to take any action, and then, when stringency was acute, contented themselves with importing petroleum, and made but half-hearted and sometimes very ill-advised attemps to obtain supplies at home.

Advances in Research

The position is now somewhat different. Research has continued and has been giving results far in advance of anything hitherto achieved: the extraction of oil from retortable material is on a surer basis than ever before, and it is to this source of supply rather than to the development of oil-fields, that the writer wishes to draw attention.

The chief advances recently made are in our knowledge of retorting processes, and in the discovery of new methods of dealing with crude oils. Yields from retorts much better than those obtained by the late Petroleum Research Department have been got from the same materials, and this not on an experimental or laboratory scale, but in regular works practice dealing with large quantities. The difficulties of dealing with very rich material, which is apt to clog or choke the retort, have been successfully overcome. And there are two or three hydrogenation processes in operation by which it is said that not only light oils and petrol can be made cheaply from heavy crude oils, but the sulphur content can be greatly decreased, if not eliminated. These discoveries open up vast possibilities, the effects of which can hardly be gauged at present. Heavy oil may become more valuable than light, the sulphur bogey may be exorcised, and retorted oil may hold its own against free oil in all countries that are not favoured by nature with supplies of the latter.

Torbanite the Best Material for Distillation

It is to torbanites that we must look first, and later to cannels and oil-shales, for much of our Imperial supplies. Torbanites, as the richest source, must take first place. These interesting and little understood deposits have been studied very carefully in recent years, and research is still proceeding. Fortunately, the Empire is well supplied with them.

In New South Wales, the richest torbanite in the world, capable of yielding upwards of 130 gallons of oil per ton, has been worked for many years, but, unfortunately, the work has now been shut down, partly on account of the seam thinning out, but largely because old-fashioned methods of retorting were used that gave little more than 100 gallons per ton, and were, in addition, immensely expensive in operation. In South Africa, torbanite of excellent quality has been proved over a large area in the Ermelo district, and estimates of several millions of tons have been made. This torbanite yields some 90 gallons to the ton, and the quality of the crude oil is very good. In these two countries there is *no* indigenous oil to compete with that obtained by retorting, and all petroleum supplies have to be imported. There is not the least doubt that their deposits could be exploited so as to return handsome profits.

Torbanite in Nova Scotia

In Nova Scotia, seams of torbanite have been known for many years in the coalfields near New Glasgow. Some of these seams are very rich, good for from 50 to 80 gallons per ton; others, though very thick, are of poorer quality, but can be worked by quarrying instead of mining. None of them is being worked at present. In Great Britain, many torbanites of various degrees of richness were discovered by research work during the War, and torbanitic cannels were proved over a large area. A fairly complete survey was made of such retortable material, and sites were actually selected for retorting works, but little or nothing is being done at present to utilize such valuable material. Recent retorting tests on a large scale have shown that very good quality crude oil can be obtained from English and Scottish torbanites and cannels, and good prices can be realized.

Here, then, are undeveloped resources that are well worth the attention of anyone who has at heart the policy of making the Empire as far as possible self-supporting. In Australia, though one company has ceased operations, other and thicker seams of wonderful torbanite are known, but are not being worked. In South Africa the value of the torbanite seams is at last being appreciated, and active development will soon follow. In Nova Scotia, though

competition with imported oil will have to be faced, there is a great field for development, and excellent prospects of success.

New Interest in Great Britain

Even in conservative Britain, where several unsuccessful attempts have been made to start a retorting industry, the truth is gradually becoming known, and the value of torbanitic deposits learnt. The time-worn criticism that a thing cannot be done because it has never been done before has ceased to carry much weight in industrial circles. To develop Imperial resources of oil is the aim; and all these countries can contribute to what will amount in the end to a very respectable total. And the easiest and best material to deal with first of all is torbanite. Ordinary cannels and oil-shales will come later.

An Imperial Conference has been sitting in London. Among the delegates may we hope to find a statesman far-seeing enough to view the situation from an Imperial standpoint, and vigorous enough to translate his schemes into action, one whose voice will command a world-wide hearing as he thunders "Who will dare to laugh at torbanite now?"

THE USES OF MICA

As an insulating material in electrical apparatus and machinery sheet mica is used extensively. In fact, its most important use is in the electrical industry, where a non inflammable, resistant insulting material is necessary. Nearly every piece of apparatus and machinery utilizing electricity must have mica for insulation. In its resistance to puncture, infusibility, and imperviousness to moisture mica is an ideal insulator, and in addition it has physical properties—cleavage, transparency, toughness, hardness, elasticity, flexibility, and resonance—which are not found combined in any other substance. It is therefore serviceable for a variety of purposes, such as an electric insulating material in condensers for magnetos for the engines of automobiles, trucks, and airplanes; in condensers for radio-transmission apparatus; and in spark plugs for automobiles, trucks, and airplanes. Condenser mica must be clear, must split easily and smoothly into films as thin as one-thousandth of an inch, and must be free from cracks, holes, foreign substances, stains, spots, and smoke, and the sheets must be plane and smooth, free from waves, wrinkles, reeves, rulings, or knots.

Sheet mica and splittings are used as insulating material in the form of sheets, washers, and tubes in dynamos and in numerous electric fittings and appliances, such as electric heating devices,, electric-light sockets, spark plugs, guards in rheostats, fuse boxes and telephones. Flexible cloth and tape, partly made of or covered with mica, find varied uses in electric apparatus. Sheet mica is used for glazing in the fronts of stoves, in furnace sightholes, for screens in front of highly heated material, for optical lanterns as a retarder of heat waves, and for making lamp chimneys and lamp shades.

Amber Mica for Commutators

As an insulator between the copper segments of the commutators for direct-current dynamos and motors phlogopite or "amber" mica is said to be preferred, as muscovite or "white" mica, being harder, does not wear down evenly with the copper, leaving a ridge above the copper bar that would cause sparking and irregular running. For all other insulation, however, the domestic muscovite is satisfactory.

Phonograph or diaphragm mica must be of a very high grade, for it must be clear and transparent and must also be flat.

Mica for lamp chimneys and canopies must be clear and must split easily and be very flexible. Very little domestic mica can be used for this purpose. Indian and Brazilian mica are used instead.

For stove fronts a nearly clear mica, hard and rigid, is most desirable, and much of the North Carolina mica, especially the greenish, is well adapted for this use.

Mica Board

Sheet mica of an inferior grade and splittings (mostly in the form of built-up mica board) are also extensively used for general electric insulation. Muscovite and phlogopite mica are both suitable for building into mica board. This material is prepared by splitting the mica into thin sheets, systematically placing them together with shellac, and then subjecting the whole to pressure. In this way large composite sheets are made, which are as suitable as single sheets of mica for some insulating purposes. The mica boards manufactured by different concerns are known by special trade names, such as "micanite," "micasbeston," and "micabond."

Most of the mica splittings produced are consumed in the manufacture of built-up mica board, but some splittings are used as such in making mica tubes for spark-plug cores and other insulating uses, wrapping for wire coils, and insulating tape.

Ground Mica

Scrap mica, or mica that can not be utilized as sheet or splittings, is ground and sold in powdered form. Ground mica, usually coarsely ground, is used in patent roofing compositions, and for this purpose biotite or black mica is also suitable. The mica serves the purpose of keeping the material from sticking when rolled for shipping or storage. Ground mica is also used for decoration, chiefly in wall paper, fancy paint, ornamental tile, and concrete facings; as a lubricant; in annealing steel; and as an absorbent for nitroglycerin. Its heat-resisting qualities render it useful in railroad car-axle packings, in pipe and boiler covering, in fireproof paints, and in rubber tires. Nearly all the mica ground in the United States is obtained from the mining and manufacturing of sheet mica, being the waste obtained in mining and the waste and trimmings resulting from the cutting of the sheet mica. — U. S. G. S. Report for 1922.

THE STORY OF CEMENT

The Portland Cement Association, Chicago, which includes in its membership Canadian as well as [illegible] manufacturers, has issued a [illegible] entitled "Conquering Our Continent [illegible] Industry" by Edward Hungerford [illegible] American writer. In this Mr. Hungerford gives, in a vivid and non-technical style, the story of this vast [illegible]. He tells how the Concrete Age [illegible] out that, from a production of a million barrels of [illegible] in 1890, the output of [illegible] has risen to [illegible]. We must [illegible] glance about us wherever we happen to be, in city, farm or highway, to see the innumerable uses to which this cement is put. A recent advance in cement mill practice is the installation of waste heat [illegible] able of providing almost all the power required for the plant.

A Review of Canada's Mineral Industry

Prepared by the Mines Branch Department of Mines, for the National Resources Intelligence Service

The Natural Resources Intelligence Service, Ottawa, has just issued a most interesting and informing 220-page book, with illustrations and a map, entitled "Canada—Natural Resources and Commerce." Its object is well stated in the foreword thus:

"The Dominion of Canada is relatively a newcomer to the field of foreign commerce on an extensive scale. Her natural resources are still largely undeveloped, and by no means thoroughly known or appreciated even by Canadians. But the rapid exploitation of the past twenty years has clearly and strikingly revealed the national domain to be such—both in character and in extent—that its full utilization must inevitably spell for Canada a wide career in international trade, rather than an unique degree of self-sufficiency.

"With full appreciation of this all-important fact, the present volume, purposely very general and restricted in scope, has been prepared especially to afford those associated with international trade a concise review of the natural resources of Canada, and of the broad features which they impart to the commerce of the Dominion by their limitations as well as by their diversity and abundance."

The section on minerals and mining, which fills 24 pages, has been prepared by the Mines Branch of the Department of Mines. It gives an excellent bird's-eye view of Canada's mineral industry, and is reproduced hereunder.

Importance of Mineral Production

The importance of mineral resources in the economic structure of a nation has been vastly magnified in modern times, and has given rise to the axiom that coal and iron are the basis of industrial strength and progress. To coal and iron must now be added petroleum. In the possession of these three essentials of modern civilization, the continent of North America stands preëminent amongst the world's geographical areas. Canada, occupying the northern half of North America shares in the possession of enormous resources of coal in large resources of low grade iron ores which are already on the verge of successful commercial exploitation, and, it is confidently hoped, in great potential resources in oil.

It is, however, in respect to other products that Canada has hitherto contributed most heavily to the world's markets. Long before the exceptional production stimulated by the war, the Dominion had become the world's principal source of nickel, asbestos and cobalt, and an important producer of gold, silver, copper, lead, zinc, and a number of the rarer metals. Few countries possess greater coal resources, and the Canadian output of arsenic, chromite, feldspar, graphite, gypsum, mica, magnesite, pyrites, and talc stands high in records of the world's production. The mining areas of Cariboo, Klondike, Rossland, Anyox, Britannia Bay, Salmon River, Alice Arm, Portland Canal, Sudbury, Cobalt, Porcupine, Kirkland Lake, and, more recently, the newer gold areas in Ontario and Quebec, and the copper-gold-silver camps in Northern Manitoba have become familiar in the world's mineral markets.

The discovery of each new mineral district has been followed by great stimulation in mining activity, which, supplemented by the more prosaic mining of coal, asbestos, gypsum, salt, and the numerous other non-metallic products, has resulted in rapid increase in the total annual value of Canada's mineral production during the past thirty years.

The close of the war was naturally followed by a period of readjustment, involving semi-stagnation in the production of such metals as nickel, copper, lead and zinc, as well as in other minerals. The year 1920 showed a quick reaction to increased output, particularly of non-metallics and structural products, resulting in a total value of production greater than that of any previous year. This high level was not maintained, and a further depression in metal output, especially copper and nickel, with lower prices for silver, reduced the total value for 1921 to a figure below that of any of the previous five years. Good, silver and lead outputs advanced decidedly during the past year and, while copper and nickel remained low, the mineral production for 1922 reached a total value surpassed only in two or three exceptional years. The details for the principal items in the output for 1922 indicate the diversity of Canada's mining development.

The value of the mining industry to the Dominion is reflected only in a very general manner by the monetary sum of the total output, or by the variety of mineral products. Perhaps the best indication of its im

Annual Value of Mineral Production

Year	Metallic	Fuel and other non-metallics	Clay products and other structural materials, cement, lime, stone, etc.	Total
1890	$ 3,610,000	$ 9,140,000	$ 3,760,000	[illegible]*

portance as a national asset and as a source of economic strength is furnished by the fact that the mining industry is credited with over 35 per cent of the total tonnage carried by Canadian railways. It is significant to note also that, as a result of the wide distribution of mineral resources, five of the nine provinces of the Dominion share substantially in mining activity, although Ontario leads her sister provinces by a considerable margin.

Mineral Production by Provinces, 1922

Province	Value of production	Per cent of total
Nova Scotia	$ 28,804,474	15.69
New Brunswick	2,414,152	1.31

Total	183,630,139	100.0

Distribution of Minerals

Eastern Canada.—Important deposits of coal, iron, gold and gypsum are mined or quarried in the Atlantic coast province of Nova Scotia. There is a considerable production of clay products, limestone for furnace flux, and sandstone for building purposes and for grindstones. Granite and manganese, antimony, tripolite, barite and salt are also mined, while some attention has been paid to copper and lead ores.

The most important mining development in Nova Scotia is in coal, and upon this based the large iron and steel industries of Sydney and New Glasgow. The iron ores are brought from the Wabana mines in Newfoundland. The close association here of one of the largest iron ore deposits in the world with enormous coal resources and necessary fluxes, all conveniently situated on the Atlantic seaboard, may well become in future a controlling factor in a large portion of the world's iron and steel trade.

Mineral Production of Nova Scotia, 1920

	Quantity	Value $
Coal, tons	6,429,291	32,238,129
Gypsum, tons	260,661	573,752
Clay products	.....	541,114
Stone	.....	420,175
Other products	.....	356,847
Total	.....	34,130,017

* To illustrate the diversity of mineral output in the various provinces the statistics for 1920 are used in preference to those for 1921, as the latter cover a period of depression in certain branches of the mining industry .

Mineral development in New Brunswick is less prominent. This is partly due to the covering of soil and to the forested areas which make prospecting difficult. The principal mineral products are iron, gypsum, natural gas, lime, coal, building material, grindstones, clays and mineral water. Antimony, manganese and albertite have been important, while copper, lead, silver, nickel, gold and other minerals have been found. Shales rich in oils and ammonium salts occur in large quantity.

Ontario and Quebec.—The main asbestos mines of the world are found in the southeastern portion of Quebec, and other important industries are carried on in chrome iron ore, copper, pyrites and the quarrying of granite. Iron ores and gold also occur.

Within the past year prospecting for gold has been very active in Rouyn township and adjoining area in Timiskaming county, northwestern Quebec. Important discoveries have been made and their encouraging nature has led to the staking of many thousands of acres of mining land. The geology of the area is somewhat similar to that of the well known Kirkland Lake district.

The southern portion of Ontario and the valley of the St. Lawrence, designated as the St. Lawrence Lowlands, are covered mainly by flat lying Paleozoic rocks. The mineral products include clay, cement, slate, lime, limestone and sandstone, petroleum, natural gas, salt, gypsum and other non-metallic products.

Mineral Wealth of Huge Laurentian Plateau

The country extending from Labrador on the east, enclosing the Hudson Bay basin, and referred to as the Laurentian Plateau region, consists of a huge U-shaped area of pre-Cambrian rocks, estimated to cover 2,000,000 square miles, or over one-half of Canada. This region occupies nearly all but the most southern portions of the provinces of Quebec, Ontario and Manitoba.

The rocks of the pre-Cambrian are remarkable for the variety of their useful and valuable mineral deposits. Iron, copper, nickel, cobalt, silver, gold, plati-

num and palladium, molybdenum, lead, zinc, arsenic, pyrites, mica, apatite, graphite, feldspar, fluorspar, quartz, talc, actinolite, the rare earths, ornamental stones and gems, building materials, etc., are all found, and are, or have been, profitably mined. Most of the other materials — both common and rare — that are used in the arts, have been found.

The mineral output of the province of Ontario is unusually diversified. Along the southern edge of the Laurentian Plateau region in Canada there are the known gold ranges of the Lake of the Woods, the silver of Thunder Bay, a succession of iron ranges extending from Minnesota for hundreds of miles to Quebec, copper rocks of Michipicoten and Bruce mines; the Sudbury copper-nickel deposits; the Montreal River and Cobalt silver areas; the Porcupine, Larder Lake and Kirkland Lake gold fields; the corundum deposits of eastern Ontario; the magnetites of eastern Ontario and Quebec, and their large apatite-mica deposits.

In recent years the outstanding feature of the Ontario mineral industry has been the rapid increase in gold production. Gold mining in Ontario has extended over half a century but has made its chief progress since 1911, owing particularly to the Porcupine and, to a less extent, to the Kirkland Lake areas. The output for 1922 reached approximately one million ounces, valued in excess of $20,000,000. There is ample

Gold Production of Northern Ontario, 1918-1922

1918	$ 8,502,480
1919	$10,451,709
1920	$11,686,043
1921	$14,624,085
1922	$20,668,692

evidence that Ontario's gold production will probably double in the next few years and, added to the production of silver, nickel, copper and numerous other minerals which have been mined extensively for many years, will give the province a very high rank among the world's principal mineral producing areas.

Manitoba and Saskatchewan. The western end of the pre-Cambrian region extends across the northern portion of Manitoba and Saskatchewan. Prospecting in these provinces has already been rewarded by important discoveries. Numerous claims have been staked for gold, and several mines are under development, but the most important discoveries have been the copper-zinc sulphide deposits at Flin-Flon lake and Schist lake. The Mandy mine at Schist lake has already shipped a considerable tonnage of high grade copper ore, and the Flin-Flon property has been extensively drilled, proving an ore body of about 16,000,000 tons. With transportation and smelting facilities provided, a large mineral area may be actively developed, but as yet Manitoba and Saskatchewan do not possess extensive mining activity.

It is a safe assumption that this great northern area, still almost entirely unexplored and but slightly prospected, contains vast stores of mineral wealth which will become available as the country is opened up.

The Interior Continental Plain. This area includes the greater portions of Manitoba and Saskatchewan which lie outside of the pre-Cambrian, and the province of Alberta. It is pre-eminently agricultural, but in addition to furnishing an important market for the product of the mine, will have a large output of non-metallic minerals. It is underlain for the greater part by sedimentary rocks, chiefly of Cretaceous age, containing coal, building stones, clays and cement materials. The lignite of the more easterly plains, useful for local purposes, becomes more highly bituminous as the mountains are approached. The known coal reserves in Alberta are greater than in any other province, being estimated at 1,072,627 millions of metric tons. Natural gas occurs over wide areas, and there is every indication of the existence of oil fields. Intensive prospecting for oil is now being carried on by large Canadian and British corporations. Enormous deposits of tar sands have been found in northern Alberta, gold in a number of the rivers coming from the mountains, and clay ironstone occurrences in many parts of the Northwest.

Coal has been the principal product in Alberta and Saskatchewan, and natural gas has been extensively used for many years in the former province. Gypsum has long been quarried in Manitoba, and salt was also formerly recovered from brines. Drilling for salt is now in progress in Alberta. Natural deposits of sodium sulphate in Saskatchewan and Alberta are attracting considerable attention, and a beginning has been made in marketing the product. The white clays of southern Saskatchewan are being used for the manufacture of more or less refractory products, and will eventually be the basis of large ceramic industries.

British Columbia and the Yukon. The Cordilleran belt in South America, in Mexico and in the Western States, is recognized as one of the greatest mining regions of the world, noted principally for its wealth in gold, silver, copper and lead.

In Canada this belt has a length of 1,300 miles, a width of 400 miles, and its rocks range from the oldest formations to the youngest. It is not only rich in gold, silver, copper, lead and zinc, but has enormous resources of coal of excellent quality, varying from lignites to anthracite. Though mostly unprospected, it has already been proved to possess immense coal fields, several of the greatest copper and silver-lead mines, one of the greatest zinc mines, and two of the greatest placer camps in western America.

The coal fields of the Crowsnest Pass district, and the coking ovens at Fernie and Michel, have supplied fuel for the smelting industries of southern British

Columbia and of the adjacent states to the south. The Vancouver Island coal mines have supplied metallurgical fuel and domestic and steam coal for home consumption and for export.

Metal Mining in British Columbia

The metalliferous ores of British Columbia are highly complex. Hitherto the production of silver-lead-zinc ores has predominated in the Kootenay districts, gold-copper ores at Rossland, low-grade copper ores in the "Boundary district", and copper ores on the coast. In the Sullivan mine at Kimberley upwards of 6,000,000 tons of lead and zinc ore are claimed to have been developed, from which a large tonnage is shipped annually. At Trail a series of smelting and refining plants produce refined gold and silver, electrolytic lead, copper and zinc. The Rossland camp has had a varied history. Its ores are primarily gold ores, supplemented by a small copper content. Recent improvements in ore concentration methods and extensive ore development seem to ensure many years of further successful operation. At the Copper Mountain properties, near Princeton, a large mill has been erected, the concentrates being sent to Trail for smelting.

On the coast enormous bodies of copper ores have been developed at Britannia Bay and at Anyox. At the latter point a large smelting plant, in operation since 1914, is now producing upwards of 30,000,000 pounds of copper per annum. A complete by-product coking plant has been erected, the operating company having acquired its own coal areas on Vancouver Island. The new 2,500-ton mill at the Britannia Mine is treating 2,300 tons per day and will also produce at the rate of about 30,000,000 pounds of copper per year in the form of copper concentrates. Various properties on the coast give promise of large silver and gold production, while iron ores have been found at different points on the coast and in the interior. The Salmon River-Portland Canal area has gained world wide fame following the success of the Premier gold-silver mine, which has paid dividends of $3,650,000 up to April, 1923, after about three years' operations.

The Yukon district has held attention in the past chiefly because of its rich gold placers. Copper, silver and lead ores have been mined, however, and many other metals have been found. Coal has been found both in the southern and northern areas. At present attention is being centred on phenomenally rich silver-lead ores near Mayo.

The Northwest Territories are believed to possess great latent mineral resources. Those to which attention has already been directed include the native copper of the Coppermine River country, the iron ores of Belcher Island, gold and zinc near Great Slave lake and petroleum in the Mackenzie River basin below Fort Norman.

External Trade in Mineral Products

A very large portion of the mineral production of Canada is exported for consumption or refining outside of Canada. On the other hand, considerable quantities of mine products are imported, chiefly those which have been refined or subjected to partial treatment, or in the form of manufactured goods ready for consumption. For economic or geographic reasons Canada is also a heavy importer of coal and iron. Sufficient domestic resources of petroleum have not yet been developed, and tin is obtained entirely from abroad.

The total values of exports and imports of mineral products, crude or refined, and of manufactured mine products is shown for a number of years in the Table below. As these figures include manufactured goods they are not comparable to the mineral production records.

External Trade in Mineral Products, Crude and Refined, and Manufactured Mine Products, 1913-1921.

Calender year	Exports of Canadian Merchandise	Imports for consumption	Excess of imports over exports
	$		$
1913	79,804,000	259,300,000	179,496,000
1914	75,533,000	181,676,000	106,143,000
1915	124,158,000	146,465,000	22,307,000
1916	178,575,000	256,347,000	77,772,000
1917	187,894,000	355,928,000	168,034,000
1918	180,083,000	347,682,000	167,599,000
1919	179,958,000	330,711,000	150,753,000
1920	193,420,000	496,380,000	302,960,000
1921	92,357,000	303,522,000	211,165,000
Total, 1913-1921	1,291,782,000	2,678,011,000	1,386,229,000
Annual aver., 1913-1921	143,531,000	297,556,000	154,025,000

It will be observed that Canada figures much more prominently in foreign markets as a buyer than as a seller of commodities of mineral origin. On the interchange of such products the Dominion normally incurs a heavy adverse balance. Her mineral resources and industries support a large volume of export sales but several factors have combined to build up a much greater volume of purchases.

Mineral Imports

Canada's mineral purchases from abroad annually include a wide variety of products but the aggregate value is accounted for largely by three items — iron and steel goods, coal and petroleum. It is significant to note that, of the total mineral imports during 1920, amounting to over $482,000,000, about $250,000,000, or more than half, was contributed by iron and steel products, and over $151,000,000, or approximately 31 per cent, by coal, coke and petroleum.

The size of Canada's annual bill for mineral imports does not merely reflect the fact that native resources of coal, iron ore and petroleum have for one reason or another fallen short of meeting domestic needs. There is the further fact that a large portion of the imports is taken in the form of highly manufactured products, such as machinery, implements and automobiles. Thus the monetary sum of the Dominion's mineral purchases is perhaps due less to limitations in basic mineral resources and industries than to the necessarily moderate size of [illegible] settled country can strengthen its facilities for specialized manufacture.

Mineral Exports

Of the total exports in 1920 about $60,000,000 can be attributed to metals, either in crude or refined metallic form or contained in ores or some form of metallurgical product exported for further refining

These include pig iron, ferro-alloys, steel billets and ingots, aluminium, cobalt, copper, lead, nickel, zinc, and gold and silver. About $38,000,000 is attributed to asbestos, coal, mica, and various other non-metallic minerals, and approximately $12,000,000 represents chemical products, such as cyanamide, calcium carbide, ammonium sulphate, etc. The balance of over $83,000,000 is made up largely of manufactured products, chiefly manufactures of iron and steel, such as agricultural implements, machinery, boilers and locomotives, automobiles, steel rolling mill products, and wire.

Future Development

The future development of mineral industries will undoubtedly go hand in hand with the growth of population, the advance of settlement and the extension of transportation facilities. Their rate of progress promises to surpass that of the past quarter of a century. During that period both the metallurgical and chemical industries made great strides, but it was also true that mineral resources in Canada were forced to face severe competition. They had to offer exceptional promise in order to attract any great share of development funds and enterprise. Very strong inducements were being held out in other directions—by agricultural lands, pulpwood areas and waterpowers, which have yielded good returns with relative freedom from the element of risk.

There is now every evidence that Canada has already entered upon a new period of development and that, in future, mineral resources will receive and generously reward a much greater share of attention than they formerly enjoyed. Such a course of industrial growth will be strictly in accord with the economic needs of the Dominion and with the unanimous belief in the nature and wealth of its hidden physical resources.

Letters From Readers

The Rochester Property

To the Editor,
Canadian Mining Journal,

In your News and Comments (issue of November 16th there is an article headed "Canadel, oh Canadel" by Alexander Gray.

This has been answered in part by Mr. Frank Loring, who deals fully with the organization of the different companies and their objects. There are, however, several statements made by Mr. Gray which should be corrected.

In the first place, the Rochester is not a Veteran claim, as it was a tract of some 185 acres staked shortly after the Hollinger.

Secondly, the statement as to the price is not correct and should be $275,000. This Mr. Gray could have ascertained had he taken the trouble to consult the writer.

I have just returned from an examination of the property and the work done since its purchase reflects great credit on those in charge.

The veins discovered in the drift at the 100-foot level and those tapped by the shaft now at a depth of 900 feet give it all the earmarks of a producer in the near future, and we are in no way exercised as to future payments, as these veins would more than warrant the company exercising their option.

Ottawa, Ont. D. B. Rochester.

The experimental use of liquid oxygen in Colorad has shown it to cost about half as much as dynamite

PERSONAL AND GENERAL

Mr. D. G. Sinclair has been appointed assistant in spector of mines for the Province of Ontario with headquarters for the present at Sudbury. Mr. Sin clair graduated from the University of Toronto in min ing engineering in 1913 and was attached to the en gineering staff of the International Nickel Company of Canada, later becoming chief surveyor at the Creigh ton Mine. Following this he was made shift boss a the Creighton Mine, which position he held for five years previous to being appointed inspector of mines

Dr. W. L. Goodwin is holding the first prospectors class for this season at Coniston. His winter tour o behalf of the Ontario Department of Mines will tak him later to the other centres of mining activity i the province, [illegible] the majority of th prospectors gather for the winter months.

Mr. D. H. MacDougall paid a professional visit t Cobalt recently.

Mr. Cyril W. Knight, geologist of Nipissing Min spent three weeks in the Rouyn-Boischatel gold regi of northwestern Quebec, studying the geology of th area, before the freeze-up made further field wor impracticable.

THE MOTION PICTURE AS AN AID TO RESEARCH

Professor H. E. T. Haultain's recent lecture tour the United States has stimulated the following editor al comment in [illegible]

Theoretical details of many mechanical operation that constitute the essential phases of chemical eng neering processes have long remained matters f conjecture and dispute. This is particularly true regard to the operation and motion of grinding me in mills that are inclosed, making visual obser at difficult or impossible. Furthermore, the human ey although able to register the picture of an insta taneous action, is incapable of following the many ste that make up that action, or of grasping fully t changes that occur in minute intervals of time. such event the motion picture camera may be used register each successive movement, the timing of p jection being arranged according to the effect desir

In this connection it is interesting to note the markable work being done by Prof. H. E. T. Hault and associates at Toronto University, the results whose researches to date, crystallized in the form of series of motion pictures, provide ample food f thought. Slow-motion projection of photographs of glass-sided cylindrical mill in action show that commonly accepted mathematical conception of t operation is at fault—that the balls travel up the s of the mill at a uniform rate of speed, then make parabolic descent to the liner at the bottom, leaving space between the paths of elevation and fall. At n mal rates of speed the motion picture shows that the balls are in contact with one another in every p of the charge; no space exists between the rising umn and the falling column. In fact, near the of the mass there appears to be an inactive zone, wh little movement of the media is observable. It is al interesting to note that a distinct segregation of t smaller balls occurs in this central zone. This although inexplicable, aids in the efficient operat of the mill. Outside the inactive zone the rubbing ball on ball is apparent, emphasizing the logic of st

ing abrasive grinding as the dominant action in the mill.

Since the tube mill was borrowed from the cement industry in 1895 for the grinding of sulphotelluride gold ore it has undergone only minor modifications in design, but the necessity for operating wet has deflected attention to many efficiency factors and suggested experimentation and research; these include ball load, speed of mill in relation to diameter, moisture content and volume of pulp. Most of the problems involved have been solved satisfactorily, and it is believed that the experiments now being made at Toronto University will throw fresh light on the subject of the scope of such a machine for the pulverization of a great variety of mineral and chemical products.

RECORD COAL OUTPUT IN ALBERTA EXPECTED

The year 1923 will see a new record in Alberta coal production. It is expected the total production for the year will reach 7,000,000 tons, in comparison with less than 6,000,000 last year. The production up to November 1, is 1,500,000 tons greater than the production of the same period last year. The record production previously was in 1920, when 6,400,000 tons was produced. The payroll this year, it is expected, will be over $18,000,000.

SUCCESSFUL CARBONIZATION PLANT

It is reported in *Chemistry and Industry* that the "Coalite" plant of Low Temperature Carbonization, Ltd., near Barnsley, England, is a complete success. It has been in operation on a commercial basis since 1921, and its success is such that a 500-ton plant is to be erected there, and similar plants in various parts of the country. The raw coal is carbonized at a temperature of 1,000 deg. F. The products from a ton of average coal are 1,400 lbs. of "coalite", a superior, smokeless fuel; 4,500 to 6,000 cubic feet of gas (700 to 825 B.t.u.); 18 to 20 gal. of low-temperature oils; and 15 lb. sulphate of ammonia.

AIR DRILLS MAKE RECORD AT SHAWINIGAN FALLS

In carrying out their operations at Shawinigan Falls, Que., the Grenville Crushed Rock Company has to deal with rock consisting of soft and hard layers of granite full of slips and with products of white quartz scattered throughout. The layers of granite vary greatly in hardness, sometimes cutting freely for four or five feet and then running hard from four to six feet. These facts are mentioned in order that the following figures may be duly gauged.

The company has on this job three Leyner-Ingersoll X-70 rock drills, and since the first of these tools was employed the management has kept a record of their performances. The results are decidedly suggestive, and show what can be done under unfavourable circumstances. During the month of July last, an exact record of the footage drill and time consumed was kept for each drill. All the machines were fitted with standard 1¼-inch, hollow, round steels, with "Leyner" shanks. The starter bits were of 2⅞-inch diameter, and ⅛-inch changes on 24-inch runs were used. The depth of holes were drilled to a depth of 28 feet. The air pressure employed ranged from 80 to 85 pounds. The thing that must be borne in mind is that the character of the ground made drilling at times extremely difficult because the rock prevented the rotation of the steels; and two of the drills had to contend with material on this sort for considerable periods. Work was carried on in 8-hour shifts.

Drilling Record

Date	Drill No. 1	Drill No. 2	Drill No. 3.
July 1	83 ft.		
2	75		
3	62		
4	72		
5	62		
6	76		
7	76	54 ft.	
8	67	65	
9	80	64	
10	76	75	12 ft.
11	64	74	52
12	82	76	96
13	92	105	103
14	78	86	104
16	75	74	89
17	98	84	110
18	87	74	64
19	78	66	96
20	79	53	103
21	74	70	70
23	88	75	104
24	80	85	111
26	43	60	83
28	80	65	85
29	70	55	
30	49	45	52
31	60	55	52
	2,008	1,460	1,386
Average per hour	9.3 ft.	8.7	10.2 ft.

General average 9.4 ft.

Considering frequent delays caused by bad ground, etc., the foregoing record is remarkable. There were no breakages of any sort; and on six different days drill No. 3 drilled more than 100 feet.

MAP OF CHU CHUA

The Geological Survey, Ottawa, has published a topographic map on a scale of a mile to the inch, with 100-foot contour intervals, of the Chu Chua map area in the North Thompson Valley, B.C. The recent development of coal seams in this area and the success that has attended the development of the Windpass property make the new map of direct commercial interest.

SOUTH AFRICAN ASBESTOS MINING DEPRESSED

Reports from South Africa indicate that the disorganized state of industry in Europe, and particularly in Germany, is having a decidedly adverse effect on asbestos mining, which is in a depressed state, with abnormally low prices quoted.

LUCKY JIM MINE TO REOPEN

It is reported that A. Larson and associates have bought the Lucky Jim Mine at Zincton, near Nelson, B.C., and that they will proceed to develop and work it immediately.

METAL MARKETS

Prices in carload lots, f.o.b. Montreal, as quoted by Consolidated M. & S. Co.)

Average for week ending December 11

Electrolytic copper	15.00
Zinc	7.85
Lead	7.875

THE MINING DISTRICTS

By THE JOURNAL'S CORRESPONDENTS

QUEBEC

Assay Office for Gold-Field.—The Quebec government has taken measures to provide a public assay office for the use of those working in the gold belt. J. T. Donald & Co. of Montreal have undertaken to place an assayer at Angliers, the end of steel on the Quinze river. A winter road is being cut from there northward, which it is expected will provide the easiest and most economical route to the gold area. With the opening of navigation next spring it is intended to run small steamers regularly on the water route northward from Angliers, one from the end of steel to the 1,000-foot portage at the foot of Barrière Lake, and the other through Barrière lake, Lonely river and Lake Opasatika to the north end of the last, where it touches the gold belt near Lake Fortune. This is a first-class water route, and will allow of a regular and inexpensive transportation service. It is, therefore, a logical decision to place an assay office at Angliers, which will be the principal "jumping-off place." The provincial government has undertaken to make good to Messrs. Donald & Co., any deficit they may incur while establishing their laboratory. There is a possibility that, if there is sufficient demand, a general testing laboratory may be developed, in addition to the assaying laboratory that constitutes the first item on the programme.

NORTHERN ONTARIO

South Lorrain. — The Mining Corporation is meeting with particularly favorable results in its development at the Frontier mine in South Lorrain. The main shaft was completed to the 6th level only a short time ago, and crosscutting started from the 5th and 6th levels. On the 5th level, within about 50 feet of the shaft, the Watson vein was encountered, where it showed an average of about 11 inches of 5,000-ounce ore. While the Watson vein is an extremely important one, the company expects that even better results will be met with in the development of the Woods vein at depth, as this is the most important ore-bearing fissure in the South Lorrain district. It is probable that the Woods vein will be encountered on both the 5th and 6th levels some time during December.

Shareholders in the Wettlaufer Silver Mines are being circularized for their proxies by J. F. H. Ussher, a mining broker of Toronto. Proxies are being requested with the idea of calling a meeting of the shareholders for the purpose of electing a new board of directors, who would show more interest in the property. Hopes are held out that the property may again become a producer, and Mr. Ussher promises, if successful, to have the mine unwatered and a thorough examination made by competent engineers.

Cobalt. — The Nipissing has declared the regular quarterly dividend of 3 per cent, with bonus of 3 per cent, payable January 21st to shareholders of record December 31st. Developments at this property have been very favorable, and, as a matter of fact, the company is producing high-grade concentrate faster than the plant and refinery are able to treat it. At present there is over 100 tons of concentrate that has been stored awaiting treatment. The company is in an extremely strong position, their net current assets amounting to approximately $4,700,000.

Anglo Canadian Explorers, which is an organization controlled by John Taylor & Sons, of London, has taken an option on a group of claims in the Gillies Limit, adjoining those held by the Mining Corporation. It is not expected that the company will do much work at present, as it is considered advisable to see what results are obtained by the Mining Corporation before going to any great expense. This same company has an option on the Kirkland Townsite property, on which diamond-drilling is being done. Favorable results have been encountered in the drilling, and a contract has been let to sink a shaft to a depth of 400 feet to confirm the drilling results by underground development.

Larder. — The Associated Goldfields in Larder Lake will continue the shaft on the Pancake Lake property from 750 feet to the 1,000-foot level, and will open up two new levels at 875 feet and 1,000 feet. Practically all the work to date has been done above the 500-foot level, and results have been similiar to those on the Crown Reserve property adjoining. It is to be hoped that some day these two properties, which are on the same veins, will be amalgamated. One mill could easily handle the ore from both properties and many economies could be effected by their being worked together. While the claim owned by the Associated Goldfields appears to be a valuable one, it is not big enough to support the capital of $30,000,000, which the Associated Goldfields has.

Kirkland. — During the month of October the Lake Shore treated 2,146 tons, and recovered $49,270, an average of $23.40 a ton. Work on the new mill has been severely handicapped by delayed delivery of materials and also by freight congestion, so that the company will probably not be able to increase its milling capacity until about next March.

Recent newspaper reports regarding the Montreal-Ontario seem to have official sanction for the statement that conditions at this property are very favorable. These reports, however, are not confirmed by men who are familiar with what is going on in Kirkland, who seem to have an entirely different opinion from that expressed in the press reports. The Montreal-Ontario has had an unfortunate history and it is greatly to be hoped that there will be no repetition of the fiasco which occurred when the mill was started. Either less publicity or else a complete statement regarding real conditions would be a good thing.

Porcupine. Underground work has been started on the Edwards property, which lies to the West of the West Dome Lake Mines. The incline shaft, which is down approximately 50 feet, will be continued to the 200-foot level. There is a promising surface exposure on which the shaft was sunk, which gave encouraging values, although they were hardly of sufficient grade to constitute payable ore. One big mining company

diamond-drilled the property a few years ago, but did not consider the results sufficiently encouraging to justify any extensive work. The development of the property is being financed by English interests.

The Vipond mill has started operations and it is expected to treat approximately 150 tons a day of $10.00 ore. This property, which is controlled by English interests, has staged a remarkable "comeback," the results of development work done during the current year having entirely altered the complexion of affairs. It is understood that developments underground continue to be favorable, and that there are for ore reserves several years already blocked out.

BRITISH COLUMBIA

Cedar Creek Litigation Settled. — The exploitation of rich placer leases on Cedar Creek, Cariboo, has been held up recently by litigation. The circumstances leading up to this were as follows: The "Big Six" mining syndicate, so called, made up of the original locators, sold to F. S. Munson of Seattle and associates for $180,000. The latter formed the Cedar Creek Mining Co. which proceeded to operate and took out, it is said, at least as much as the purchase price in gold values. On August 1st 1923, however, they were in default $60,000 owing to the "Big Six" and sixty-seven workmen had filed mechanics' liens against the property for $20,000 due in wages. Shortly prior to August 1st the Prudential Trust Co. of Vancouver were appointed receivers on behalf of all the creditors including the mechanic lien holders. Subsequent to that date notice of cancellation under the bond of the agreement was served by the "Big Six" and an attempt made to resume possession of the property. Confronted by the agent of the Prudential Trust Co. the representatives of the "Big Six" turned to the Courts for redress. Settlement, however, according to the announcement of A. S. Matthew, president of the Cedar Creek Mining Co., has been effected out of court, payment in full having been made to the first locators. Mr. Matthew is authority for the statement that nothing now stands in the way of the uninterrupted operation of the leases. Recent reports respecting the latter are bright. In breaking new ground high returns have been secured. Recovery is expensive because of scarcity of water, the ground being on the high levels; but the gold content, judging from authoritative reports, is such that a good profit is assured.

Stewart. — The Daly Alaska mineral claims, Portland Canal district, are to be further developed. Work is to proceed during the winter on a 500-foot tunnel, the object of which is to cut at depth the several veins outcropping on the property.

The property of the Indian Mines Ltd., Salmon River, is expected to pass definitely from the prospect stage to that of a shipping mine as a result of this winter's work. A raise in No. 1 Tunnel is reported to be up some 30 feet following a high-grade shoot of ore some three to four feet wide averaging about $100 in gold and silver values. This raise will be continued through to the surface, a distance of 280 feet, in order not only to extract the high-grade ore but to furnish ventilation for No. 1 and the lower tunnels. This raise is in Drift 15 and it is interesting to note that this and Drift 13 are in the same ore-body, the former following a high-grade gold shoot and the latter a high-grade silver shoot, the values of the latter being in sulphides. Diamond-drilling has proven the continuity of the body of ore in which these shoots occur. There is to be further diamond-drilling and tunneling during the next few months and the management is looking forward to being in shape to ship at least some high-grade ore with the opening of the 1924 season.

Smithers. — The Babine Bonanza property, near Smithers, has been closed down for the winter. James Cronin, the owner, states that this year's work has consisted of drifting on the main vein. At 200 feet a shoot of good ore has been opened up, thus removing all doubt as to the persistence of the ore at depth. Mr. Cronin contemplates the installation of a concentrator and other mine plant necessary to active mining operations. He has left to spend the winter in Spokane.

Usk. — S. A. Davis, with whom is associated a syndicate of business men of Seattle, is reported to have bonded the Lucky Luke Group of mineral claims situated close to the town of Usk on the National Railway, nothern British Columbia. This is not far from the Duthie properties, which have been taken over by the Guggenheims and which have been showing up extremely well. The Lucky Luke is said to be a first-class prospect, the ore being quartz mineralized with bornite and chalcopyrite and carrying from $30 to $37.50 in gold per ton in addition to its copper and silver values. It is a fissure vein from 1½ to 3 feet wide striking obliquely along the east slope of the Kitselas Mountain in a schisted zone in which also are found, to the north, the high-grade gold-copper veins of the Kitselas Mountain Copper Co. A winter road is to be constructed from the property to the railroad, a distance of a quarter of a mile, and a carload of ore is to be shipped as soon as the road is ready.

Peace River Coal.—J. D. Galloway, resident mining engineer at Hazelton, is visiting Victoria after an inspection tour of mining properties in the Peace River and the Cariboo districts. He speaks in the highest terms of the coal deposits of the Peace River, which he says are extensive and of very high grade, running in most cases 70 per cent. fixed carbon and 3 per cent. ash. Apart altogether from the grain and general agricultural possibilities of the district. Mr. Galloway thinks that its coal resources assure it a notable future.

Improved Coal Trade.—The coal trade of British Columbia has improved during the last two months. This is due chiefly to the growing domestic demand for fuel. It applies more to the collieries of the Coast than to those of the eastern section of the province. The mines of Vancouver Island had a good month in October. They are expected to have an equally satisfactory output for November. In the Nicola-Princeton field there has been considerable activity and it is reported that a new mine is to be opened up at an early date. News from the Crow's Nest Pass field, however, is not so bright. It is stated that the competition of fuel oil is making serious inroads into the business of the Crow's Nest Pass Coal Co. and the Corbin Coal & Coke Co. Much of the railway trade has been lost to these companies through the conversion of most of the locomotives into oil burners. At present, it is stated, the mines at Coal Creek have been working two and three days a week. Some domestic coke is being produced at Michel, which has been of

some help to that community. Generally, however, the business may be said to have a better tone than was the case four months ago and the provincial production for the year should compare favorably with that of last year.

Tax on Fuel Oil.—One of the outstanding events of the past week from the viewpoint of coal mine operators and employees was the announcement in the budget speech of the Hon. John Hart, Minister of Finance, to the Legislative Assembly of the Province that a tax of one-half a cent per gallon would be placed on foreign fuel oil consumed in British Columbia. This is a policy that has long been advocated by Hon. Wm. Sloan, Minister of Mines, who represents the coal mining town of Nanaimo, Vancouver Island, in the Legislature. He has taken advantage of every opportunity to dwell publicly on the effect of the constantly growing use of fuel oil for industrial and domestic purposes in the province on the local coal mining industry. He is given credit for having influenced the government to adopt this measure. It is hoped by the coal mining fraternity that its application will afford them some relief.

Strike at Collieries.—Employees of the Sterling and the Coal Valley Mines, near Coal Spur, Alberta, are on strike. Mine officials state that the dispute is not so much one of wages as their determination to keep their mines out of U. M. W. of A. control.

Success at Windpass Mine. — The discovery of high-grade gold-bearing ore at the Windpass Mine, Chu Chua, about sixty miles north of the city of Kamloops on the Canadian National Railway is pronounced by Mr A. W. Davis, the Government Mining Engineer, to be the most noteworthy event of the year in the central interior of British Columbia.

Some two years ago, this property was bonded by the late General R. G. Edwardes Leckie, with whom were associated Messrs. Trites, Wood and Wilson of Fernie, who, it will be recalled, met with their first outstanding mining success in the opening up of the Premier Mine, and the subsequent transfer of a majority interest in the mine to the Guggenheims. General Leckie carried on vigorous development for a year or more. Two shafts have been sunk and connected with an old adit level on the vein at a depth of 100 feet below surface. The tragedy of the story is that General Leckie died before it became known that his judgment and faith had been justified.

The removal of the prime mover in the enterprise did not alter the determination of his associates to see it through to a definite issue one way or the other. Now, as has been indicated, their perseverance has been rewarded. Within the last few months, the vein has been sufficiently developed to indicate that this prospect will likely become a mine.

The Windpass vein lies in a diorite sill; it is partly quartzose, but largely a replacement of wall rock by magnetite, chalcopyrite and pyrrhotite. Bismuth and a gold telluride occur. The ore probably is primary. At present preparations are being made for more extensive development.

MAPLE BAY ORE MOVING

The Maple Bay mine, Portland Canal, may possibly ship one or two cargoes of ore to the Granby smelter at Anyox; but it is not likely regular shipments will commence until the first of the year.

NOVA SCOTIA

Pension Fund Committee—Following the announcement of President Roy Wolvin of an old age pension scheme for the workmen of the corporation the following committee has been appointed to administer the fund: H. J. McCann, General Manager Besco coal, Chairman; W. H. Bischoff, General Superintendent of the Steel company, Vice-chairman; A. W. McDonald, Superintendent of Industrials Relations, Secretary; M. A. Doak, comptroller:—all of Sydney; Archie McColl, Manager, Nova Scotia Steel & Coal Co., New Glasgow and J. E. McLurg, Manager of the Shipyards, Halifax.

The first meeting was held for organization purposes. It is understood this committee will have large powers and may not at the beginning be restricted to the conditions stated by Mr. Wolvin when he first gave public notice of the pension scheme. After the first list has been prepared and accepted the work will automatically carry on; but at the beginning there will, no doubt, be cases requiring sound judgment and common sense on the part of the Committee. As the Committee represents the heads of the different departments and as each member has his own individual gifts and qualities for department administration, the pension fund will be in the hands of the strong men of the corporation.

Pensions will Benefit Company Also—The popularity of the scheme is general and both the workmen and the public are beginning to revise their opinions of the B. E. S. Corporation. There is little doubt that more faithful service will be given and there will be more loyalty, due to the benefits of this fund..

We are not, however, blind to the fact that the Corporation will profit materially by the adoption of the pension scheme. Indeed, ever since mining began in Nova Scotia (and it is no doubt true of most other employment) the older workers have been cared for. The different companies have found employment of some kind for the old men and these, up to a very recent period, were all kept at work. The Compensation Act with its startling statistics of accidents has led to searching investigations, which throw light on the whole subject of accidents, and it has been found that age has much to do with liability to accident. Still, there will be plenty of room among the younger men for those of the "old guard" who remain hale and hearty.

Nova Scotia at the Exhibition—The exhibit of the British Empire Steel Corporation for the British Empire Exhibition at Wembley Park, London, next year, was shipped to Ottawa recently. It took upwards of four months to assemble all the material and get ready the charts and plans showing the natural resources of this great Corporation, its plants, railways, piers, ships and minerals and their products.

The great variety of manufactured products, the raw materials such as iron ore, limestone, coal have all been artistically arranged and form a most striking display. Pig iron, steel billets, blooms and ingots, rails, wire rods, barbed and other kinds of wire, seventy different kinds of nails, silica brick, coke and by-products of coal, these are only part of the exhibit. A suspicious looking little box contains six vials labelled Road Oil, Tar Crude Naptholene, Sulphate of Ammonia, Motor Fuel Solvent Naphtha, C. P. Toluol and C. P. Benzol,—all by-products of coal.

The facilities of the Corporation for storing, handling and shipping material are represented by photographs. Views are seen of the Halifax Shipyards and

shipe built there, Halifax Dry Dock, Sydney Steel Plant with its shipping piers, loading and discharging, the shipping piers of North Sydney, Pictou and Parrsboro. There are maps of the coal areas of Cape Breton showing all collieries and coal seams, also maps of Newfoundland showing the iron ore properties and ore mining plants, as well as the limestone quarries at Port au Basque.

The extent of the Corporation's natural resources is indicated by the following figures:

	Reserve tons	Annual production tons
Coal	6,000,000,000	6,000,000
Iron Ore	6,900,000,000	1,200,000
Limestone	150,000,000	600,000
Silica	40,000,000	10,000

The annual capacity of the Sydney steel plant is 350,000 ingot-tons, and of the Sydney Mines plant, 144,000 ingot-tons.

Wage Negotiations in Progress—Negotiations on the new wage agreement opened last week when the Executive of the United Mine Workers met in the office of General Manager H. J. McCann. A statement was given out that no report of the proceedings would be made public until the agreement has been drawn up. The Corporation has notified the United Mine Workers of its desire to terminate the present agreement, and there is considerable anxiety among the workmen as to what is behind the action. Something must be done to train larger numbers of young men for work at the face, and the Corporation may have this problem in mind. The present agreement was made under the pressure of strike conditions and can be much improved, from the points of view both of the miners and the management.

IMPROVED KINCAID WATER WHEELS DEVELOP ECONOMICAL and EFFICIENT POWER FOR MINES

The "KINCAID" water-wheels deliver the full theoretical power calculated from a given quantity of water from a stated head.

Using the best materials combined with careful workmanship results in the "KINCAID" being a water-wheel as near mechanical perfection as it is possible to make it. Let us demonstrate its possibilities to you.

For men

For machinery

YOU provide cabinets well stocked with bandages and liniments for "first aid" when an employee cuts a finger, breaks an arm, or suffers other injury. In the majority of cases the injury does not require further attention beyond the limits of the "first aid" cabinet.

Are you using a "first aid" outfit for broken machinery?

A chipped cog, a crack in a pulley or shaft can be fixed on the spot, often without tearing down the machine, by the use of a welding outfit.

A cylinder of Dominion Oxygen and a cylinder of Prest-O-Lite Dissolved Acetylene mounted on a handy truck, together with an Oxy-acetylene Torch, will enable you to make many repairs with but little loss of time and at small cost. It is to your machinery what the "medicine chest" is to your men—"first aid" when accidents occur.

Let us show you how to save money by making economical repairs to machinery by using Dominion Service. A call by telephone or mail will promptly bring one of our representatives.

Breaking Through !

This is a red letter day on any rock drilling project and one that has been speeded up in thousands of instances by Leyner-Ingersoll Rock Drills.

No rock drill stands the test of time unless it does better work at less cost. Design, material and workmanship all play an important part in the performance and upkeep cost of rock drilling equipment.

An examination of the cost records of thousands of rock drilling jobs under almost every conceivable sort of condition would reveal the fact that Leyner-Ingersoll Drills cost less to operate per actual foot of hole drilled.

If you want rock drilling equipment that will meet your needs in every way put your problem up to our nearest branch.

Standardization

The Keystone of Dodge Service in Power Transmission Machinery

We have the capital, the experience, the equipment and the distributive power to justify our manufacturing for stock a quantity of every Power Transmission Unit. We can do this because Dodge lines are standard equipment in a majority of Canadian plants. Buyers can rely upon securing from us, at a moment's notice, any quantity and any size of the following standard lines:

Pulleys (—Wood—Iron—Steel) Countershaft Fixtures
Shafting. . . . . .Hangers Friction Clutches
Couplings. . . . . .Bearings Belt Conveyors
Brackets. . . . . .Bushings Chain
Pillow Blocks. . . . .Sprocket Gearing
Belting (Leather and Rubber) Rope (all kinds)

Send us your rush orders and watch how well we shall serve you.

Special note to Dealers: If you would like to secure an appointment as local stocker of Dodge lines, write to us for full particulars.

Ontario's Minerals

PROVINCE OF ONTARIO

Hon. CHARLES. McCREA, Minister. DEPARTMENT OF MINES *Thos. W. Gibson*

Mineral Areas

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favourable for the occurrence of minerals 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver veins of Cobalt, Gowganda and South Lorrain occur in these rocks; so also do the far-famed nickel-copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

Economic Minerals

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario: — actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluorspar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, Portland cement, brick and tile, meet every demand.

Mineral Production

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1922 to be worth $62,202,169, of which the metallic production was $38,190,711.

The following figures show the growth of Ontario's mineral industry by five-year periods since 1891 when a Bureau of Mines was first established.

Year.	Value.	Year.	Value.
1891	$4,705,672	1911	$41,976,797
1896	5,235,003	1916	65,303,822
1901	11,831,086	1918 (Maximum war output)	80,308,972
1906	22,388,383	1921	48,128,387
	Dividends.		

Dividends and bonuses paid to the end of 1922 amounted to $28,096,699 for gold mining companies, and $86,238,185 for silver mining companies or a total of $114,334,884.

Mining Regulations

A miner's license costs $5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of $2.50 or $3.00 per acre, depending on location in unsurveyed or surveyed territory.

Assay Office

The Provincial Assays Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

Graphite, by H. S. Spence.

Gas Producer Trials with Alberta Coals, by J. Blizard and E. S. Malloch.

The Mines Branch maintains the following laboratories in which investigations are made with a view to assisting in the developing of the general mining industry of Canada:—

Fuel Testing Laboratory.—Testing value of Canadian fuels for steam raising and production of power gas; analyses, and other chemical and physical examinations of solid, liquid and gaseous fuels are also made.

Ore-Dressing Laboratory.—Testing of Canadian ores and minerals, to ascertain most economical methods of treatment.

Chemical Laboratory.—Analyzing and assaying of all mineral substances and their manufactured products. Copies of schedules of fees, which are lightly in excess of those charged by private practitioners, may be had on application.

Ceramic Laboratory.—Equipment is such that complete physical tests on clays and shales of the Dominion can be made, to determine their value from an economic standpoint.

Structural Materials Laboratory.—Experimental work on sands, cements and limes is also undertaken.

Applications for reports and particulars relative to having investigations made in the several laboratories should be addressed to **The Director, Mines Branch, Department of Mines, Ottawa.**

:-: A MERRY CHRISTMAS :-:

A CHRISTMAS MESSAGE

In viewing the great problems that face the world to-day, one cannot but be struck by the divergence of views that are held and by the pertinacity with which opposing factions adhere to their tenets. Indeed, it would appear as though some strange distortion of the facts of life were militating to-day against a straightforward solution of our many problems, and one is tempted to inquire whether there are grounds for this conclusion.

The many avenues of progress that lie before modern men have led them in diverging directions. Some of these roads still point forward, some go off at a tangent, and some even turn backward. As a result a multiplicity of viewpoints has been adopted by various persons, families, classes, and even nations, each secure in the conviction that his or their particular viewpoint is the right one, and that others are wrong.

Particularly in these days of specialization, when intensive effort tends to hedge itself about with the litter from its own progress, do we find it increasingly difficult to preserve a common viewpoint; we see our own point too well and the other man's, too little. In other words, the tendency is to lose one's sense of perspective, and for lack of it many a discussion or conference ends where it began. We vastly enjoy discussions, they present such admirable opportunities for the ventilation of ideas; but the trouble is that, generally speaking, the ventilation is too good and a draught results that carries the ideas *in tenues auras*. Regulated ventilation is one thing; a whirlwind is quite another, as it is proverbially destructive.

Some form of guidance towards a common end is necessary in this conflict of ideas, and when we see the number of divergent views increasing and the weight of opinion swaying this way and that towards some unseen goal, without consistent direction and with much lost motion, it is surely evidence that, somehow or other, we have lost our sense of perspective.

We may state quite definitely that perspective is no more than a name unless it involves a common understanding and a united aim. A sense of perspective involves the ability to see ahead, which is the peculiar faculty that inspires initiative. It was the late Elbert Hubbard who remarked that Initiative shared with a Rich Pa the chief responsibility for the deliverance of a boy from the attack of Destiny, waiting around the corner with a Stuffed Club.

Not to everyone is given the power both to see and to do; but perception is the prior requisite.

Initiative is a dangerous attribute without proper guidance; and if our intensive studies and our scientific achievements have loaded us with such a burden of responsibility and have blinded us with such magnificence of discovery that we cannot lift our heads and look forward, to see where we are going, we are in danger of disaster. When a ship is launched, there must be no wobbling and the ways must be well greased, lest the auspicious event be marked only by bubbles at the end.

We are about to launch upon a New Year. The attractions and distractions that characterize present-day life are bewildering in their kaleidoscopic variety. No man among us can tell how the turn of events may fashion even his own individual view; we all think we are right,—but what is the truth?

There is an erroneous idea that democracy calls for the untrammeled growth of individual opinion, that freedom comes before the law; but that is not the way of nature. There is *purpose* in all the works of nature, just as there is a vanishing point to every picture; and we shall never have our picture in perspective until a common purpose directs our actions.

There is no industry that does not suffer from the unsettled conditions in the world to-day. We ardently desire a full measure of prosperity in our mining industry; but we know full well that this can be no more than a dream until there is at least a partial settlement in the conflict of nations, creeds and parties. It is singleness of purpose alone that will bring order out of the chaos to which man's inventive powers have led.

[illegible] PEACE AND GOODWILL TOWARDS MEN.

ALL-LAND ROAD TO GOLD-FIELD ASSURED

[illegible] discretion and with dispatch. Last week we noticed in these columns the faulty location of the new winter road from Angliers on the Quinze river northward to the gold belt. The contract for cutting this road specified the foot of Lake Opasatika as its terminus, and

it was intended to use the ice of the lake for the remaining sixteen miles. As we go to press we learn that Hon. J. E. Perrault has authorized an all-land route, and that orders have gone forward to the contractor now engaged on the road to continue it to Boischatel township, where it will join the present east-west road. Mr. Perrault is to be congratulated on the promptitude with which he has attended to this matter.

PLATINUM IN SOUTH AFRICA

Two weeks ago we printed an account by Mr. Max Bauman of the discovery by himself and associates of a platinum-bearing "reef" in South Africa, about one hundred miles north of Pretoria. This was from a paper presented before the Chemical, Metallurgical and Mining Society of South Africa, and was couched in most moderate terms, with plenty of substantial evidence for the conclusions drawn, and full warrant for the deductions. In brief, it described a vein or series of veins, several miles in length, in which the preliminary prospecting work then accomplished indicated shoots of payable platinum ore. The ore is described as brecciated quartz filling a fracture zone in felsite rock in the Bushveld complex. Today we print some additional descriptions, from other sources.

Platinum is one of the most difficult metals to determine by assay or analysis. There are probably not over half-a-dozen assayers in Canada who can be depended upon to determine it accurately in the various ores in which it occurs. It is quite possible that, as was the case with nickel thirty years ago, its presence in payable quantities has been overlooked, even here inCanada, where its occurrence in the Sudbury ores should keep us on the look-out for it. The new find in the Transvaal, demonstrating an unsuspected occurrence of the precious metal, may well result in a closer search and similar discoveries in other parts of the world, particularly here in Canada, where the great intrusive igneous mass underlying the Bushveld is duplicated on a smaller scale at Sudbury, and is simulated in other parts of our pre-Cambrian area.

PEAT FUELS, LIMITED

Last month we announced the fact that a supply of peat fuel is assured for the season of 1924, through private enterprise. Mr. Kennedy Stinson, of Montreal, has given his personal bond to the Dominion government and has acquired the peat manufacturing plant at Alfred, Ontario, on undertaking to put it in operation by May of next year. Mr. E. V. Moore, formerly engineer for the Peat Committee, has completed the plans required to change the plant from steam to electric drive, as recommended in the final report of the Peat Committee, and peat fuel to the amount of at least 15,000 tons and of the same superior quality as that made in 1922 will be available to the public.

While the Peat Committee was still operating the plant at Alfred, Mr. Stinson, who conducts a wholesale and retail fuel business in addition to other commercial activities, offered to buy the whole output of the plant. He and his associates have decided now, however, to adopt a more liberal policy of distribution than this during their first season as private operators. Since the people of Ontario paid a large part of the $350,000 required to conduct the experiments of the Peat Committee, they are to have the refusal of a large part of the 1924 output. The sale of the entire output for next year is already guaranteed by large orders; but the small users who already have shown their interest in peat by buying it are to have first chance.

Peat Fuels, Limited, has been organized by Messrs. Stinson and Moore and some associates, to operate the plant at Alfred in the first instance, and then to build and operate additional plants at strategic points as circumstances may direct. In other words, the express object of Peat Fuels is to develop a peat industry in Ontario and Quebec, commencing at the Alfred bog. This will be done either by increasing the capital stock of the present company or by forming subsidiaries. What dimensions the peat industry will assume finally, only time will tell; but many of us who have investigated the plant and have used the fuel are confident that it will replace much of the anthracite used at present.

Peat Fuels, Limited, have now offered for public subscription $85,000 of 7 per cent. preference stock, with a bonus of common stock, with a view to meeting the expense of altering the peat plant to electric drive and making it ready to operate next spring. We have examined into their proposals as carefully as we can, and find that they are sound and equitable in every respect. The financial return to the promoters of the project will come almost entirely from dividends on common stock (of which they will hold the majority of the shares), after preference dividends have been paid. They themselves are taking most of the risk (such as it is); they ask the public to join them.

The new company is commencing its career under unusually favourable auspices. It has been demonstrated to the satisfaction of the Peat Committee, the Deputy Ministers of Mines at Ottawa and Toronto, and all others who have taken the trouble to examine at first hand the data available, that peat fuel can be made by the Anrep-Moore process for $3.50 per ton, on the cars—a cost that will allow of a good profit at competitive selling prices. Two governments are sympathetically disposed towards the project, and have recommended it unequivocally to the public. The Quebec government has offered a bonus for the production

f peat fuel within the province. The company now wns all the patents, plans and other assets formerly eld by Mr. Moore and his associates in the peat roject. The company has the financial backing and he practical advice and guidance of one of Montreal's uccessful business men, who has followed closely the ork of the Peat Committee from beginning to end.

Few new business undertakings commence under uch favourable auspices as Peat Fuels. We can re- ommend it without qualification to the attention of he investing public.

"DUMPING" OF AMERICAN COAL IN WINNIPEG

Mr. George R. Pratt, representative of the govern- nent of Alberta in Winnipeg on behalf of Alberta oal producers, continues his vigorous protests against he "dumping" of American coal in Manitoba, where he price has been cut below that at which the Alberta perators can make a profit. He points out, in a letter ecently to the Winnipeg *Tribune*, that these Am- erican coal men are certainly not philanthropists, and that they expect to make up in the future the loss incurred by this price-cutting. Certain Manitoban officials are pluming themselves for having saved an amount estimated to be $225,000, by buying cheap Am erican coal — a direct result of the effort of Mr. Pratt and his associates to introduce Alberta coal. It is a shortsighted bargain they have made.

Mr. Pratt points out that small consumers, that is the general public, have not benefited by a corres- ponding reduction in the price of their fuel. The same dealers who have cut prices on the government con- tracts are holding up their prices to top notch so far as domestic consumers are concerned.

This may well be a case requiring special investiga- tion by a public authority. American coal is being sold deliberately and openly to the government of Manitoba at rates lower than those across the border in the United States. We have "anti-dumping" laws to protect some of our industries. Cannot these be used to prevent this unfair competition against Alberta coal in Winnipeg?

THE STAKING REGULATIONS IN QUEBEC

A letter from two prospectors in Rouyn township, Quebec, Messrs. MacDonald and Thompson, which ap- pears on another page, sets forth the "land grabbing" propensity of a number of trained mining men who have been operating in the district. This is given, ap- parently, as an excuse for the same fault among pros- pectors; but of course it is inexcusable under any cir- cumstance to "blanket" land to such an extent as to exclude possible neighbors who might assist in ex- ploring and opening up the district.

Messrs. MacDonald and Thompson have a peculiar right to discuss this matter. They are among the best known prospectors in the north country, and have not been greedy in staking. Mr. MacDonald particularly works like a beaver on his claims, and withal finds time to entertain a wide circle of friends, so that "Bert's" cabin in the woods has something of the nature of a rustic hotel, with the notable difference that he will never accept anything but thanks for his hospitality.

This wholesale staking of land in "rush" localities is not of itself particularly objectionable, except inso- far as it gives too large a share of the public domain to one man, merely for his ability to run across the country and plant stakes. The serious thing is that by this means large tracts of land that ought to be prospected are often withheld from development, from either the inability or the disinclination of the owner to do the necessary work or have it done.

There are various reasons why much valuable pros- pecting ground in the Quebec gold belt has been, and still is, thus withheld from useful development. One reason is that some of those who hold land are simply waiting for their neighbors to make a strike, that they may then "turn over" their property at a profit. Min- ing companies and prospectors alike indulge in this practice, as well as self-confessed speculators. Another reason is that some well-intentioned companies or in- dividuals, who are able and willing to investigate their properties, do not feel that the time has yet arrived to spend the money to do it; they are willing that someone else should do the pioneering. Still another reason, which applies principally to professional claim stakers and less often to real prospectors, is that they sometimes ask an exorbitant figure for their proper- ties and, being unable or unwilling to investigate the ground themselves, are thus in the position of the dog in the manger.

This "blanketing" and "land-grabbing" is a habit confined to no particular section of the mining and prospecting fraternities, and is reprehensible in all cases. Land must be pre-empted for prospecting by staking, under present conditions; but it should be neither "hogged" nor withheld from development. The regulations at present in force allow of both, and should be amended to prevent either. The administra- tion of the Bureau of Mines at Quebec are investigat- ing the matter, and no doubt more effective measures will be enacted at the next session of the legislature.

SPECTACULAR GOLD SPECIMENS

The rush to Fournière and Malartic townships, just to the west of Lac de Montigny and 65 to 70 miles east of the interprovincial boundary along the gold belt in Quebec, was stimulated by some spectacular spe- cimens of ore brought out to Quebec a few weeks ago, coupled with a report that geological conditions favour- able to the occurrence of payable ore had been found there. The specimens (for they were not samples, strictly speaking) showed an unusual proportion of coarse gold.

Secondary Enrichment at Keeley Mine

By J. MACKINTOSH BELL

A Study of Deep Weathering in this Famous Silver Mine

A further study of the oxidized zones in the Keeley Mine, South Lorrain, Ontario, was given recently by Dr. J. Mackintosh Bell in a paper before the Society of Economic Geologists, and is published in the October-November number of *Economic Geology*. From it the following is abstracted:

One at least of the oxidized sections at the Keeley is not shallow, but has been followed downward level by level and is still conspicuous at the deepest horizon yet attained, namely, 480 feet. (Since writing this paper, a new horizon at 560 feet has been developed to some extent, and it is noteworthy that the oxidation still continues in the section in question.)

What is the reason for this relatively deep oxidation — so unsual in a region which has been generally so intensely glaciated? What effect has the oxidation had upon the segregation of values?

Topography.

The Keeley mine is situated in the district of South Lorrain, about sixteen miles southeast of Cobalt, of which it forms a geological outlier, and to which it is subsidiary from a commercial standpoint. The mine lies on the crest of hills nearly 600 feet above and about three miles west of Lake Timiskaming. The rise from Lake Timiskaming is not steady, the intervening country being broken by several ridges separated by relatively deep valleys containing lakes and streams. These valleys have commonly a general parallelism to the main axis of the adjacent portion of Lake Timiskaming.

Southwestward of the Keeley is the deep basin of Trout Lake, with its main axis again lying north and south or approximately that of Lake Timiskaming. Both the eastern and western shores are high and abrupt, but from its northeastern bay a depression in the hills radiates northeastward, and another northward, through and beyond the Keeley properly. From the nothwestern bay, a third but less marked depression passes northwesterly. These various topographical features require emphasis in view of the fact that certain of them have apparently a marked bearing on the problems presented.

General Geology.

Though the depressions of the 80-acre tract covered by the Keeley mine are relatively deeply filled with boulder clay and much of the rest of the property shrouded in similar glacial debris, exposures of solid rock are of common occurrence. These consist of Keewatin rocks, lamprophyre dikes, and Nipissing diabase, which have been so fully described elsewhere that an elaborate petrographical description need not be given.

The diabase, occurring as a wide sill, has been intruded in such manner as to assume the form of a broad dome, which has been truncated by erosion. The veins of the Keeley are associated with the westerly dipping limb of the dome and occur either in the diabase itself or in the Keewatin rocks beneath which the sill plunges.

The faulting in the vicinity of the Keeley has a marked influence on the topography, as previously indicated, and the comprehension of the latter, in suitable geological surroundings, forms an important guide to prospecting. While all the principal faulting exposed at the mine seems to have occurred mainly, at least, prior to the mineralization, it must not be supposed that conversely all the faults are mineralized.

The faults studied in the Keeley workings appear to be reverse in character, the greatest throw not exceeding fifty feet. While the faulting in South Lorrain has been, as yet, only very broadly studied, the surmise that all the minor dislocations are connected with the major movement, primarily responsible for the deep basin of Lake Timiskaming, forms an attractive and probable hypothesis, for which there is considerable supporting field evidence.

Character of the Veins.

What may be described as the "Mother Lode" of the western section of South Lorrain is Wood's vein, which has been traced in the underground workings almost across the Keeley and located also in the properties to the north and south. Along its generally north and south strike, it has a length of at least a mile. The pronounced fault which it occupies resembles the Cobalt Lake fault, in being the fracture of paramount control in influencing the distribution of the veins; but it differs therefrom in the remarkable strength of the vein-material contained and in the smaller amount of gouge. With a general parallelism to Woods occur in the Keeley a number of other north and south veins, and roughly transverse to it, a multiplicity of others.

The Keeley veins, like those of Cobalt, are ordinarily in the association and paragenesis of the minerals contained; in the origin of their ore-shoots; in their structural characteristic; and in other details, that it will be advisable here to emphasize the differences rather than to reiterate features that have already received much attention from various writers.

The Keeley veins, like those of Cobalt, are ordinarily narrow, varying in width from a few inches to a few feet. Wood's vein and certain others do not always occupy a single fracture but commonly a fractured zone, which may be from five feet to (in the case of Wood's) even ten feet in width. Within this fractured zone, vein material proper does not ordinarily extend from wall to wall, but occurs in several more or less pronounced stringers. While the intervening altered country rock may be more or less impregnated with silver values, it is frequently — even adjoining very high-grade shoots — almost barren, and in contrast to the veins in the Cobalt series at Cobalt, there is ordinarily little or no impregnation of silver values beyond the generally pronounced walls.

The Ore-Shoots

While the deposits at Cobalt occur in "narrow practically vertical fissures and joint-like cracks," those of the Keeley occupy faults along which there was pronounced dislocation prior to the deposition of the vein-material. While in the minor veins there

seems to be a tendency to the segregation of the values where the dip is vertical or approaching verticality, Wood's vein, which is the most important silver producer of the Keeley, has an average dip (easterly) of only 60 deg. and rich shoots occur where the inclination is even much flatter.

While the richest ore-shoots of the Keeley occur close to, but not exactly at the contact between the diabase and greenstone, and important ore bodies are found alike in both rocks, the vertical range over which ore extends from the contact seems to be greater than in the case of Cobalt. Thus, rich ore occurs in Wood's vein down to the lowest horizon of the mine, 480 feet (where it is wholly in diabase) or a length along the dip of not less than 550 feet, and how much greater remains to be seen.

The unaltered vein material is composed of country rock more or less replaced by carbonates (chiefly calcite but with some dolomite), quartz, and metallic minerals. The metallic minerals show the same variety as at Cobalt. Smaltite, cobaltite, chloanthite, niccolite, pyrite, marcasite, arsenopyrite, chalcopyrite, native silver, argentite, ruby silver in various forms, and native bismuth are all common. Galena and sphalerite are rarer, but are apparently more conspicuous than at Cobalt. The quantity of iron-bearing sulphides contained seems to be generally much higher than at Cobalt, and it is possible that the percentage of iron in the smaltite is greater than is ordinarily the case at Cobalt.

Weathering of Vein Material

Significant as may be the various differences between the character of the Cobalt veins and those of the Keeley, already enumerated, much more impressive is the degree to which alteration of the original vein material has taken place at the Keeley as compared with that at Cobalt. There has been great alteration by meteoric waters, in many veins in various parts of the property, to depths of 100 feet or more, while the change is so intense in the southern 500 or 600 feet of Wood's vein that it will be advisable to explain it in detail.

The first level to be opened on the portion of the vein in question was at a depth of 230 feet. Here the vein-material consists mainly of a soft, puggy clay. Where this is completely oxidized (iron-stained-brown, yellow, and red; rarely copper-stained-green and blue; and still more rarely, showing traces of cobalt bloom) the quantity of silver contained, except uncommonly in the form of thin scales, is negligible even in locations structurally suitable for its disposition. On the other hand, in the partially oxidized portions, that is, where partly in the "ferrous" rather than completely in the "ferric" state, the amount of silver present is considerable. In other words, there are shoots of mill ore with irregularly distributed values. The oxidation at the 230 foot level extends into the adjoining walls, especially the foot wall, and is equally conspicuous along No. 20 vein, which branches southeasterly from the hanging wall.

Silver Follows "Ferrous" Material

At the next level down — 300 feet — conditions are similar, though the quantity of silver contained in the "ferrous" vein-material is less important. At 360 feet the vein-material is almost wholly oxidized; there is little or no bluish pug characteristic of the "ferrous" phase, the vein fissures being filled mainly with firm brown and yellow clay, almost devoid of silver.

At 420 feet, much "ferrous" material occurs, associated with the more wide-spread "ferric," with the consequent great enrichment in silver. The demarcation between "ferrous" and "ferric" is frequently extraordinarily abrupt, but it is still noteworthy that purely "ferric" material, even a few inches away from rich "ferrous" ore, is practically valueless. The silver in the "ferrous' ore occurs in the wire form, as argentite, in spongy accumulations of tiny scaly crystals resembling miniature stalactites, and as thin plates.

At the 480-foot level, the present deepest horizon of the mine, "ferrous" vein-material predominates over "ferric," resulting in longer and more persistent ore-shoots. At this horizon much more smaltite is apparent in Wood's vein than in the levels above (especially in what seems to be only slightly altered material), but by no means in the quantity or of the same character as found in the entirely unaltered ore in other parts of the mine. In No. 20 vein, branching from the hanging wall, the vein-material is almost wholly "ferrous" and the silver unassociated with cobalt minerals, in the wire form, or in the peculiar "stalactites" that are found in the level above.

Cause of the Deep Oxidation.

The suggestion has been made that the great depth of oxidation along the southern part of Wood's vein and the lesser extent in other parts of the property may be due to climatic changes since the close of the glacial period. This hypothesis may be correct, but the writer is not inclined to view it with favor, on account of the general absence of even superficial oxidation in the district in general and because of the fact that the oxidized areas of the Keeley are invariably beneath relatively deep depressions filled with boulder clay. It is believed the oxidized sections of the veins represent rather the remnants of a generally departed zone which was mainly eroded during the glacial period.

The relatively much greater depth to which oxidation extends in the southern than in the northern part of Wood's vein is probably to be connected with a pre-glacial topography the nature of which is not now quite clear. The southern part of the depression that marks the fault occupied by Wood's vein is comparatively deep and narrow and it seems feasible to suppose that protection against corrosion was given by the hard, steep walls of greenstone on either side, especially after the depression had been filled with débris by the initial advance to the ice.

In connection with the problem, there is another factor that should not be ignored. The southern part of the Keeley property is the locus of numerous faults branching from the main Wood's fault, which continues southward to and beyond Trout Lake. The surface of the lake is quite 200 feet below that of the Wood's fault at the Keeley, while the deepest part of the bottom of the lake is probably 250 feet still lower. The section of the fault in question is the main water carrier of the Keeley at the present time, and it seems reasonable to presume that in pre-Glacial times, if not more recently, there was a subterranean connection along the fault to Trout Lake, the meteoric water descending to comparatively great depths and rising under head in the lake basin.

Effect of the Deep Oxidation

Wherever "ferric" conditions exist in the Keeley mine, and notably in the southern part of Wood's vein,

the vein -material has been almost wholly deprived of the silver content, which it may safely be assumed was originally present, in view of the general character of the vein-material under comparable structural conditions in the unaltered parts of the mine. The unoxidized vein-material is generally relatively high in iron sulphides, as previously explained. With their oxidation, sulphuric acid, and acid-ferric sulphate would be liberated, dissolving silver as sulphate according to reactions detailed by Emmons.

What little microscopic work that has been done on the Keeley ores serve to corroborate the evidence, derived from analysis and gained more particularly from the careful accumulation of geological data, that a substantial part of the silver in certain of the rich shoots of the Keeley is secondary and, is derived from the impoverished, highly oxidized upper portions of the veins. In making this statement the writer does not attempt to combat the now generally accepted theory as to the hypogene origin of the primary ore in veins of the Cobalt type, to which those of the Keeley mine clearly belong. Much of the Keeley ore is probably purely primary and has gained no enrichment from descending solutions, but in other parts of the mine, where, indeed, the richest ore has been found, there would seem no reason to doubt the existence of widespread changes, which have materially altered and enhanced the value of the primary mineralization.

QUEBEC MINISTER'S REPORT

Hon. J. E. Perrault issued at Quebec this week a report on the various governmental departments of which he is the administrative head, namely Colonization, Mines and Fisheries.

It is interesting to note that during the fiscal year 1922-23, the sum of $2,452,697.69 was spent on behalf of colonization; of this, $2,000,000 was spent under the ordinary grants and $452,697.69 out of the ordinary subsidy, and the grant allowed to colonization societies.

Of winter roads, 561.42 miles were opened and completed, 881.33 miles of bad roads rebuilt and culverts of a length of 30,000 feet constructed.

Under the act sanctioned on the 14th of February, 1920, the sum of $5,000,000 at the disposal of that department, and of this $4,536,137.06, has now been expended. With this money roads covering over 3,000 miles have been opened, completed or repaired and bridges of a length of more than 10 miles built.

The condition of the mining industry is described as having greatly improved, and the output for the year closing on the 31st of December, 1922, was $18,835,153, being an increase of 18 per cent. over the figures of the previous year.

The gold regions of the northwest of the province have attracted a great number of prospectors and have been the scene of intense activity during the whole of the year. In fact, it is one of the most considerable events of the history of the mining development of the province. Several interesting discoveries have been made, and large numbers of claims are now staked. In order to facilitate the prospectors' work, adds the report, it has been advisable to open an office at Ville Marie for the registration of claims and plans for the construction of two highways, one of which will start from the Temiscamingue or southern and the other from the Abitibi or northern side, and which will both lead to the gold districts, are under consideration.

THE VALUE OF GOLD DEVELOPMENT TO NORTHERN QUEBEC

Last week Mr. John A. Dresser, president of the Canadian Institute of Mining and Metallurgy, addressed the Reform Club of Montreal, selecting as his subject the new gold field in northern Quebec and its relation to the rest of the province and to the provincial administration. The theme is a timely one, and the interest of the assembled Montrealers, mostly business men, showed that it is popular as well.

The immediate vicinity of the gold belt, Mr. Dresser pointed out, is a triangular area of 5,000 square miles south of the Transcontinental railway, which is principally good agricultural land. Along this railway, and at the southern apex of the triangle round about Ville Marie, there are already about 20,000 inhabitants, mostly on farms. The development of the gold belt, which runs though the central and southern portions of this area for a distance of 100 miles, will hasten its settlement, and will bring prosperity in its wake, due to a good local market and high prices for farm produce.

Four mining companies, the speaker noted, are now sinking shafts, and eight other substantial companies are conducting preliminary investigations. One company has committed itself to an expenditure on its property of $200,000, and another has already spent $300,000. "In the absence of definite Government reports on the value of the area," said Mr. Dresser, "these operations are the best evidences available of the estimated value of the field by those who know it best."

Referring to the responsibility of the administration in Quebec in connection with this development, Mr. Dresser said that the province has a good mining law, but that it is as yet mainly untried and will require minor alterations. A number of questions, such as the royalty or tax on gold, have not been settled yet, simply because the point has not yet been raised.

Among the duties of the Bureau of Mines will be the prompt provision of public reports by well-qualified mining geologists and of the transportation facilities upon which progress will depend so largely. In this connection the speaker recalled the famous election in Ontario, when Premier Ross won out on his T. & N. O. policy by a majority of one, and how the result of this hard-fought election and the courageous action subsequently based on a majority of one vote, soon opened up the immensely valuable Cobalt deposits, and has since populated a section of the Great Clay Belt and started Ontario on her career of gold mining.

To the Minister of Mines at Quebec there is now presented, said Mr. Dresser, a unique opportunity. Most ministers of the Crown have to search for or create the opportunities of first-rate importance that will make them notable in the public service. The present minister has his opportunity ready to hand, and it remains for him but to grasp it, and by means of sound policies, wise administration, and prompt and vigorous action, to shape and guide the destinies of a movement that promises to be the most important in the history of Quebec.

The output of coal in the United States for the first ten months of 1923 is 456,728,000 tons, which is near that of the record year, 1918.

The Wainwright Oil and Gas Area, Alberta

By G. S. HUME, Geological Survey

The Geological Survey, Ottawa, has issued the follow-g report:

Recently British Petroleums, Ltd., brought in an oil ell near Wainwright from a sand 2,019 to 2,063 feet ep. Several wells have been drilled in this general vi-nity with the result that gas has been found in consid-able quantities at several places and the outlook is fa-ourable for further exploration.

As far as known the regional structure is a terrace, that , a flattening of the general southwest dip over a con-derable area. This produces a condition favourable to e accumulations of oil and gas. It is also probable aat minor structures, such as small domes or folds perimposed on the terrace structure, account for the calization of the oil and gas into commercial pools. The dges of the terrace structure are not well defined; in act not enough data are at hand from field work to do ore than roughly outline the terrace; but from present formation it is thought the western edge of the terrace xtends northwestward from the vicinity of Hardisty to ear Viking, where it turns more to the north. From Hardisty it probably extends southeasterly. Wainwright ould thus be on the terrace at some distance from the estern edge.

Other Wells in the District

The Imperial Oil Co. drilled a well at Fabyan, six miles orthwest of Wainwright, and in this well at a depth of ,727 feet a daily flow of 14,000,000 cu. ft. of gas was btained. A small amount of oil was present, which the seaping gas sprayed over the derrick, giving rise to eports at the time that oil had been struck. Deeper rilling encountered water.

At Irma the Gratton Creek Oil Co. drilled a hole on ec. 7 Tp. 45, Range 8, W. of 4th meridian. At a depth f 1620 feet 500,000 cu. ft. of gas was struck under a ressure of 500 lbs.

The gas field at Viking is well known, there being a umber of wells with varying but large supplies of gas. t is thought there are two gas horizons, one at about ,150 feet and the other approximately 2,350 feet. The pper horizon gives the larger flow of gas. The struc-ure in this field is supposed to be a minor dome-like old on the terrace, which would explain the concentra ion of gas.

At Vegreville a well drilled to a depth of 2,000 feet found gas at 1,360 feet amounting, according to reports, to 225,000 cu. ft. A little gas also came from a depth of 1870 feet.

In a well drilled at Birch Lake on Sec. 14, Tp. 50, Range 12 W. of 4th meridian, gas was found in a sand at a depth of 402 feet, the amount being 200,000 cu. ft. At a depth of 2,018 feet 500,000 cu. ft. were obtained.

Thus it is well established there is a large gas field in the area to the northwest of Wainwright and the oil well at Wainwright will likely lead to further exploration along the terrace structure. The oil at Wainwright is of a heavy quality, analysis showing it to contain but two and a quarter percent of gasoline. While further fav ourable structures for the accumulation of oil probably exist in this area these will necessarily be of limited area and only the wells drilled on such structures can hope for success. In other words the producing wells in this, as in other areas, are localised. Owing to the heavy mantle of drift that covers the rocks over large areas in this district, structures are not easily located so that it seems probable much test drilling will be necessary before the producing areas can be determined. Under such circumstances many wells that fail to "bring in" oil will undoubtedly be drilled, a fact which the investing public will do well to bear in mind.

Letters From Readers

The Engineer as "Land Grabber"

To the Editor,
Canadian Mining Journal.

From time to time there have appeared articles in print with attendant comment about the prospectors in Rouyn township, Quebec, who taking advantage of the 200-acre claim allowed by the Quebec Mining Act, "grabbed" all the available ground in Rouyn and adjacent townships. Such a practice, various technical men have pointed out, has had a very deleterious effect on the progress of the Rouyn section in that "with few individual prospectors holding the ground, the prospecting would be incomplete and haphazard."

It may interest your readers to know that several company "field scouts" actively participated in the snowshoe staking of last winter. In one instance two scouts staked over 40 claims, some 8,000 acres yet their companies allowed all but three or four of these claims to lapse. Most of these claims held for nine months without any field examination or assessment work, were dropped after a cursory office inspection. Surely such procedure by technical men is not conducive to the opening up of a new district!

The above staking, however, was done last winter before the era of technical disapproval. Notwithstanding the publicity given to "claim hogging," various mining engineers in the last six weeks have staked a large number of claims for their respective companies here in the Rouyn district. In several instances, in their eagerness to acquire ground they even went so far as to attempt to stake claims already located by bona-fide prospectors. One engineer deliberately cut a prospector's name from the claim posts. Unfortunately, such would-be claim jumpers cannot be handled as they would have been in the early days of the West.

As far as we can see (and we believe we voice the sentiments of the prospectors as a whole) this talk about the prospectors' staking by the technical men is merely a sort of "smoke screen" to cover their own activities. In connection with the above, they strongly urge the retention of the 50-cent per acre tax; (some even go as far as to advocate a $1.00 tax) in order to prevent the prospectors from holding any ground in Quebec.

These company officials rightly figure that the prospector's only capital is his time, while their resources, the cash surpluses earned from the mines found by the prospectors) are large. No wonder the prospector is approaching extinction.

Rouyn Township, Quebec. Fred W. Thompson.

Old Nick's Own Metal

The following resumé of the discovery and development of the vast ore-deposits of the Sudbury nickel range is based on information supplied by Mr. Thos. W. Gibson to the Engineering Foundation, New York, who have published it as Research Narrative number seventy.

In superstitious "Middle Ages" troubles were ascribed to unfriendly fairies and gnomes. Saxon miners having difficulty with certain copper ores blamed Old Nick and called the unknown troublesome ingredient kupfer-nickel, the evil spirit in copper. Nickel in old Saxon meant an obstinate person. Bactrian (province of ancient Persia) coins of 235 B. C. show by modern analysis 20 per cent. nickel. Chinese, centuries ago, used an alloy containing nickel which they called paktong (peck—white and tung —copper). It was resonant, bright in appearance and resisted corrosion well. Many gongs were made of it and it was exported to Europe. Not until 1751 was nickel isolated as a chemical element and given the old Saxon name by Cronsted, a Swedish metallurgist.

Nickel-bearing ores are found in various quarters of the globe, the greatest deposits of all, in the Sudbury district of Ontario province, not being recognized until a generation ago. They are huge "lenses" of mixed pyrrhotite and chalcopyrite and now produce 80 or 85 per cent. of the world's supply of nickel.

In 1856, a Canadian Government surveyor, Salter by name, while running a meridian northward from Lake Huron past Whitefish Lake, noted that at certain places his compass was deflected ten to twelve degrees more than the normal deflection. He reported this incident to Murray, a government geologist, who found magnetic trap rock containing traces of nickel, but did not suspect that he was walking over the greatest deposit of nickel ore in the world, so far as has yet become known. Nickel was not then in general use or in great demand. At any rate the casual observation of indications in an inaccessible wooded wilderness excited no enthusiasm among prospectors.

Grading for the Canadian Pacific Railway in 1883 revealed the mineral wealth of the region. Thomas Flanagan, blacksmith in the construction gang, noticed an area on the right-of-way covered with gossan (decomposed rock, usually reddish, owing its color mostly to pyrites). He dug holes and found copper sulphide. When railroad building progressed to this spot, a "cut" exposed the deposit. Thomas Murray and his brother William purchased the "lot" of land in 1884, but sold to H. H. Vivian and Company, of Swansea, Wales, who started the "Murray Mine" in 1889 and a furnace in 1890. Vivian and Company quit operations in 1894, selling the property later for $75,000 to J. R. Booth and M. J. O'Brien. They prospected with diamond drills and revealed a very large body of ore, subsequently estimated at eight or nine million tons. These owners in turn sold to the British-America Nickel Corporation, Ltd., which has worked the property on a larger scale. The first smelter was built in 1888 by the Canadian Copper Company, which added a second the following year.

Copper ore exposures in railroad cuts attracted many prospectors. In three or four years they located most of the important bodies yet found. Among these finds the magnetic deposit noted by Salter and Murray in 1856 was rediscovered and has become the Creighton mine, pronounced the greatest nickel mine in the world. It is operated by the International Nickel Company, successor to the Canadian Copper Company. Of the large number of mines the Vermilion arrests attention because first worked as a gold mine. In 1902, an assay showed 4 ounces of silver, 4 ounces of palladium, 1 1-2 ounces of platinum, 1-3 ounce of gold per ton and the nickel and copper contents unusually high. This deposit, however, is small.

Not until 1887 was nickel recognized in the Sudbury ores, although that is the element which has contributed most to their value. What the geologists and assayers failed to detect was perceived by the smelters. Difficulty in smelting a shipment of ore in the Orford Copper Company's works, at Constable Hook, New Jersey, led to the detection of the nickel in the company's laboratory. S. J. Ritchie, President of the Canadian Copper Company, and R. M. Thompson, President of the Orford Copper Company, happened to be in the laboratory when the discovery was made that their troubles were due to the ancient evil sprite of the Saxon miners. It was unexpected news to both men. They found that they had a great nickel deposit instead of a great copper deposit, or more correctly a great nickel and copper deposit. This discovery changed the whole situation.

Advance of the arts and sciences since 1856 has vastly increased and diversified, the demands for nickel, and this development continues. These uses range from coins, the nickel-plating of a great variety of objects, and solid nickel cooking utensils to nickel alloy steels for armor plate of battleships and important members of great modern bridges. Nickel-silver (formerly German silver) is a well known alloy of nickel, copper and zinc. Monel metal is an alloy of nickel and copper, made from the matte (an intermediate, impure product in the process of smelting) without previous separation of the metals. In North America the International Nickel Company is the greatest producer.

NICKEL ZINC

One of the many new forms in which nickel is now used is nickel zinc, made by the Apollo Metal Works, La Salle, Illinois. A brightly finished nickel plate is put on one side of sheet zinc, to which it adheres with an unusual degree of tenacity, so that bending or hammering do not cause it to peel off. This will extend the uses of both sheet zinc and nickel, particularly in the household.

HANDY MAN

An inmate of a certain penal institution recently received a call from the warden, who said:

"I understand you got in jail on account of a glowing mining prospectus."

"Yes," admitted the gentlemanly prisoner. "I was quite optimistic."

"Well," continued the warden, "the governor wants a report on conditions in this jail. I want you to write it" — Harper's.

It is expected that the McGill University exhibit for the British Empire Exhibition next summer will be ready to ship to London by the middle of January.

STORY OF THE SOUTH AFRICAN PLATINUM FIND

Mr. Max Baumann's story of the platinum find north of Pretoria, as told by himself to the members of the Chemical, Metallurgical and Mining Society of South Africa, was reproduced in abstract, in the "Journal" of December 7th. Here is the story as recounted by an on-looker, from the "S. A. Mining & Engineering Journal":

One of the most amazing discoveries in South Africa —that country of ever-fresh wonders — has slowly crept into public notice. No large headlines in the papers heralded the marvellous development which is quietly taking place in the mining world. The public has been deluded too often by the cry of platinum, and when it was stated to have been found in the obscurity of the Northern Transvaal — that hinterland populated by voortrekkers, takhaars and ragged, yet confident, prospectors — the news was received with smiles of derision. Fortune, that elusive sprite, had been so often all but in the grasp of Dolf Erasmus, who is locally supposed to have found every other mineral but platinum, therefore the old fable of "Wolf, wolf," was again proved to be true.

Early in July whispers went round Naboomspruit to the effect that the intrepid prospector of the hills had announced a new and amazing discovery, but this had occurred so constantly since the collapse of the Doornhoek tin mines that little notice was taken of it, and the sanguine, who put money into the affair, were considered insane by the more cautious. Mr. Dolf Erasmus discovered the Doornhoek tin mines sixteen years ago, and for his share received £15,000, but this was unfortunately lost, as he invested it in a farm and stock and, when tick fever devastated the country, his cattle were swept away and all his fortune with them. However, with true voortrekker courage, he was undaunted, and determined to reinstate himself and his family. He was backed by Mr. Max Baumann, a former associate at Doornhoek, and has been seeking for gold for the past four years.

One day, while panning for that metal, he came across unfamiliar traces of a silvery looking substance; this he tried to smelt on his forge, and when unsuccessful began to realise his extraordinary luck. He was not excited, but went on quietly with his quest, and, as soon as certain, conveyed the news to his friends in Johannesburg, together with the samples for their assays. He knew without their proofs that he had stumbled on an incredibly rich lode of platinum. The first revelations of 107 oz. to the ton have already been discussed, but it was thought too good to be true, and the sceptics suggested that "it should not be piled on quite so thick," even then thinking the figures meant 107 dwt. to the ton.

It is strange that Dolf Erasmus has lived on the farm Rietfontein for the greater part of his life, as he came there as a boy 30 years ago with his parents, who were previously farming at the Cape. He knows the place so well and has such a considerable knowledge of mineralogy that fate has played him a wayward trick in denying him access to the treasure so long

What the proximity of this rich lode to the little dorp of Naboomspruit is to mean to that small place can hardly yet be realised. We dreamers visualise a meteoric rise comparable with that of Johannesburg and other large mining centres. When the new road is made, the distance from the mine to the station will only be about six miles; at present a circuitous route is adopted, and the scenery on the way is exceedingly beautiful. Unless the railway extend a side line into the hills, Naboomspruit must always be the headquarters and is well adapted to its future expansion. The site is flat, but very picturesque with its large bushveld trees, and the climate is not intolerably hot in the summer. The township has already been laid out into wide streets and avenues on the American plant, and plots have doubled in value lately.

FURTHER PLATINUM REEFS REPORTED IN THE TRANSVAAL

On December 7th we published an account of some length of the new platinum discovery near Waterberg in the Transvaal, north of Pretoria. The following, from the "S. A. Mining & Engineering Journal", gives later news:

The public interest in the platinum discoveries of the Waterburg district is growing stronger every day. There are continual reports of new lode discoveries in this district at distances very far removed from the area where the deposit was first located. From Nylstroom northwards for 50 miles the lode, or at any rate, a similar lode to that found on Rietfontein No. 3, has been traced, while to the south-west of the area the same lode formation extends for many, many miles; the most recent instance being its discovery on the farm Verloren No. 2026, about three miles from Waterberg Siding. Here the outcrop is very well exposed over a long distance, the lode matter exactly corresponding to that of the Rietfontein formation. The strike is also very persistent and is quite easy to follow right across the farm. Here, again, the dip is slightly south from the vertical and makes another corresponding feature to that of the Rietfontein deposit. Quite an army of prospectors and fossickers are roving all over the Waterberg district to-day, and one may expect to hear of a number of similar discoveries in other places. It may be as well here to give a word of warning to some would-be geologists and engineers who, in their zeal for discovery of platinum lodes and due largely to their ignorance of the general and particular characteristics of this formation, are apt to mistake our old friend the Ventersdorp series for the platinum formation.

And now as to its possible extent. It would appear that the lode extends for, probably, one hundred miles north-east and south-west of the Rietfontein outcrop. It varies in direction in places due to disturbing influences which are quite obvious to the initiated, but the general direction is maintained throughout. Similarly as regards the dip, this is practically vertical everywhere. The [illegible] nature of the walls is a feature which must not be overlooked by the prospector, as this constitutes a distinguishing mark of the lode. There is a considerable amount of prospecting work going on over a wide area, and one may expect to hear of finds in places very far removed from the point of the original discovery. One such has been located over 100 miles away from Rietfontein No. 3. Samples of the formation have been assayed and show values up to 15 dwts. of platinum to the ton; but it cannot be too strongly emphasised that the whole value of the deposit still remains to be proved, and that no real mining has been attempted over most of

the area held by the different syndicates. Still, what little is known of the ore contents of the lodes is very favourable, and sufficiently encouraging to warrant further development of the propositions. After all, the proving of such a huge area will be a matter of years, and cannot possibly be determined in a few months either way.

We badly need new fields of mining in South Africa to-day. The country is rich in minerals of all kinds; this is a truism which needs no arguments to support it. There are many willing workers who want occupation and who otherwise will go to the wall. We cannot afford to pass by as worthless any possible field for development, and where the initial work already done is such as to prove a possible new mining area it ought to be, and, indeed, must be prosecuted with all the energy at our command, so as to make room for the white people of the Union to live and thrive in the land of their birth or adoption.

IMPERIAL OIL'S EXPLORATION

The Imperial Oil Company's recent progress and plans for the future in the West are summarized in the current issue of *Agricultural and Industrial Progress in Canada*, the organ of the Canadian Pacific Railway, thus:

Work on the new refinery of the Imperial Oil Co. at Calgary, Alberta, is proceeding rapidly, and by the time this article is in print will doubtless be fully ready for operations. Over 1,000 men are employed in the construction, and already there are approximately 50,000 barrels of oil in storage for refining. Future movement of "crude" to the refinery will probably come from the Wyoming field unless greater developments take place in the Southern Alberta field.

It is reported that Vice-President McQueen, who is in charge of production, has stated that the Imperial Oil Co. will not suspend operations in the Canadian North-west, and that it was the present intention of the Company to send in at least one crew to the Fort Norman with a view to deepening the Discovery Well or sink a deep hole alongside it. It is possible that work will be continued on the well at Blue Fish Creek, which is down nearly 500 ft., but which was left alone this season for lack of drilling crews. Two other wells in the district are understood to have been abandoned.

One of these, known as "C," was bored to a depth of 3,057 ft. in limestone but without a satisfactory showing; the other, "D," was drilled on Bear Island to a depth of 2,080 ft. A showing of oil was encountered at 1,945 ft. and further indications of oil and gas at 1,975. Below that, however, a small quantity of salt water was encountered.

The Discovery Well was deepened to 951 ft. and is capable of producing between 60 and 70 bbls. per day.

A new well will probably be sunk beside it next year as the original hole was too narrow to permit its easy deepening.

The Grattan or Irma No. 2 well is practically finished. Work is also in progress at the old Dingman property near Okotoks, where two new gas wells are being sunk by the Royalite subsidiary. Well No. 3 is down approximately 3,000 ft. and is reported producing 5,000,000 ft. of gas per day.

The Imperial Co. is enlarging its compression plant at Royalite to permit additional gas to be piped into Calgary, to which city it intends to supply 6,000,000 ft. of gas per day.

Work is also in progress on the Rogers leases, in which the Company holds substantial interests. These are located about four miles north of the international boundary and some twelve miles east of Coutts. Indications there are said to be encouraging.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

Toronto Meeting, 1924

It has been decided to hold the 1924 meeting of the British Association for the Advancement of Science in Canada. The sessions will begin at the University of Toronto on August 6th. and will last for one week. Following the sessions the chief excursion will be that to Western Canada and the Pacific Coast, going out by the National Railways and returning by the Canadian Pacific, or *vice versa*. Another excursion will cover the chief mining areas, pulp and paper plants, and so forth, of Northern Ontario. During the sessions there will be a number of shorter excursions, such as one to Niagara Falls and other areas of interest in the Province.

This will be the fourth Canadian meeting of this important Association, the first having been held in Montreal in 1884, the second in Toronto in 1897 and the third in Winnipeg in 1909. Only two other meetigs of the Association have been held outside the British Isles, viz., one in Australia and one in South Africa. The Association represents all branches of science; those that will be of most interest to mining men are the Section of Geology and that of Engineering.

The first annual meeting of the Association was held in 1832; this makes the Association one of the oldest, as well as one of the most influential, of scientific societies. It is expected that four or five hundred members will attend the Toronto meeting frrom overseas. There will also be a considerable attendance from the United States and, of course, from Canada. The Toronto local Secretary's Office is Room 50, Physics Building, University of Toronto.

POSITION OPEN IN MINES BRANCH

Applications will be received by the Civil Service Commission, Ottawa, up to January 3rd, 1924, for the position of Engineer in the Division of Fuels and Fuel Testing of the Mines Branch, Department of Mines. The initial salary is $2,700 per annum, to be increased by $120 annually up to $3,180. The duties are, under direction, to plan and carry out experimental tests on the combustion and carbonization of fuels and their products; to co-operate with the Technical Engineers and Chemists of the Division on the assay and valuation of solid, liquid and gaseous fuels; to inspect commercial equipment for the efficient burning and carbonization of fuels, and to design, build and operate experimental fuel testing apparatus; and to perform other related work as required.

The qualifications required are:—Education equivalent to graduation from a university of recognized standing with specialization in chemistry; preferably graduation in chemical engineering; at least four years' experience in commercial or research work connected with the Canadian industries of fuel combustion and carbonization, two years of which shall have been in a position of professional responsibility; familiarity with research methods and practice; ability to prepare for publication the results of investigations; initiative, good judgment; ability to handle men; good physical condition.

Mineral Constituents of Rand Concentrates*

By A. R. COOPER

Metallurgical practice on the Witwatersrand has recently turned from the method of removal of free gold from the ore by means of amalgamation, to the attainment of the same object by a preliminary concentration on corduroy followed by a further cleaning of the concentrate by one or more pasages over a table of the Wilfley type. The ultimate concentrate may then be treated with mercury to recover the gold, osmiridium being obtained from the tailing after barrel amalgamation and before final cyaniding or other treatment to recover the gold which may have escaped amalgamation. In the absence of osmiridium the gold may be cleaned sufficiently to allow of direct smelting.

From the inception of corduroy and Wilfley concentration it became apparent that the concentrates were often very far from being the simple mixture of gold, quartz and pyrites that association with ordinary ore samples or even black sands has led us to expect. We have long known from examination of rock specimens that occasionally pockets of such minerals as zinc blende and galena occur in the reef, the latter material being sufficiently heavy to accumulate in concentrates, but visual examination of picked specimens naturally fails to indicate the presence of minerals, which even ordinary methods of analysis would hardly reveal in unconcentrated material. Minerals occurring in the reef in such minute quantities that they have appeared to be of only slight scientific, and of no practical interest, have suddenly become important constituents of the very considerable quantities of concentrates which we handle daily. Osmiridium, once regarded merely as a special curse visited upon assayers, is now of real economic interest.

Cobalt-Nickel Arsenide

I am afraid that other minerals, which I will discuss, are quite capable of taking the place once occupied by osmiridium as a curse, not only of assayers but also of metallurgists. My first experience of one of these minerals was a sample taken from one of the mines of the Far East Rand; it was first noticed on the Wilfley tables just below the gold, and was christened the "Blue Streak". Later an enthusiastic investigator brought in a large quantity of the material with the claim that it was osmiridium, and could be obtained from one mine at least in bucketsful! It proved, however, to be an interesting arsenide of cobalt and nickel, mixed with galena and pyrites—a fruitful source of trouble and expense during smelting operations, where its habit of producing matte and speiss, the former rich in silver and gold, and the latter in platinum metals and gold, is most undesirable. It is probably also a cause of much of the coated gold and sickened amalgam met with during barrel amalgamation, especially when the material is ground to an impalpable pulp before adding the mercury. Some of this arsenic dissolves in cyanide solutions, is precipitated on the zinc and appears in acid-treated gold slime, which therefore, requires very careful roasting.

We have often listened to very interesting papers on the treatment of arsenical ores without quite realizing, I think, that we may be handling them here. I have a bottle of this arsenical concentrate for your examination, and you will notice its bluish white colour when compared with the sample of pyrites concentrate and understand how easily it can be mistaken for osmiridium.

The analysis of the material is as follows:—

	Per cent.
Arsenic	23.6
Cobalt	11.4
Nickel	3.6
Sulphur	23.7
Iron	22.8
Lead	6.8
Gold, Silver and Platinum Metals	8.1

This analysis corresponds to the mineral composition:

	Per cent.
Pyrites Fe S_2	42.3
Cobalt-Nickel Fe S_2 Iron Arsenide (Co Ni Fe) As	41.7
Galena PbS	7.9
Gold and Osmiridium	8.1

The arsenide therefore has the composition:—

	Per cent.
Arsenic	56.6
Cobalt	27.4
Nickel	8.6
Iron	7.4

This is an usual mono-arsenide corresponding to the mineral Niccolite (Ni 43.9 per cent., As 56.1 per cent.), and I cannot find any reference to an occurrence in which cobalt predominates. The galena is present commonly as very perfect crystals of cubo-octahedral form. Occasionally a small amount of the arsenic is replaced by antimony: bismuth may also be present. This material appears to be present in some quantity throughout the reef, but so far as our present information goes it is very much more plentiful in those mines east of Benoni—the Far East Rand—than in any others.

Uraninite

Another extremely interesting mineral is found in the heaviest concentrates in many mines of the group extending from the Boksburg fault west to the Central Rand: up to the present investigations have not been carried out on concentrates from the more westerly mines. This mineral is a variety of Uraninite, and a concentrate carrying a large proportion of it is shown here. It has the black colour and brilliant lustre of polished jet, and the concentrate is of the following composition:—

	Per cent.
Uranium Oxide	19.1
Thorium Oxide	1.6
Cerium Group Oxides	0.2

* From a paper read before the Chemical Metallurgical and Mining Society of South Africa.

Yttrium Group Oxides	1.5
Tellurium	Present, not determined
Calcium Oxide	Traces
Magnesium Oxide	3.3
Bismuth Oxide	0.2
Silica	1.4
Combined Water and Gases (by difference)	3.5
Aluminium, Manganese, Phosphorus, Vanadium	Traces
Copper Oxide	0.5
Lead (Pb)	8.1
Sulphur	1.1
Iron	5.0
Arsenic	5.9
Cobalt	2.3
Nickel	1.4
Gold	6.6
Mercury	2.2
Platinum and Osmiridium	4.5
Zircon	1.6
Radium	142 milligrams per ton

The radium is calculated from the ratio U: Ra is 1 :3.4x10 (Lind and Roberts, 1920); the gases helium, argon and nitrogen have not been determined. It appears that the whole of the lead is present as galena, and the cobalt, nickel and arsenic as the mineral previously described; the latter can be separated by chemical means. Mercury is probably present as small particles of amalgam not yet completely eliminated from the milling circuit. It is uncertain at present whether the bismuth is a constituent of the uraninite or not; as some evidence points to the likelihood of more bismuth being present in some concentrates than the above analysis would allow for. On one mine in the Central Rand it was noticed recently that, as the bars of mill gold solidified, they extruded some bullion in a moss-like form.

This extruded material proved to contain the following:

	Per cent.
Gold and Silver	76.0
Lead	18.4
Bismuth	4.3
Arsenic	0.8
Iron	0.2
Copper	0.3

This very easily fusible aloy, while still liquid, had been forced out by the solid and contracting gold, but it is too much to expect that it had all been so conveniently ejected and the bar of gold would be segregated and practically impossible to sample—thus providing an awkward problem to the unsuspecting official who had the task of reconciling mine and refinery assays.

Tellurium

Among the constituents of the uraninite concentrate is a small amount of tellurium. I have separated some in the metallic form, but it is very difficult to determine quantitatively owing to the extreme complexity of the concentrate. The six platinum group metals interfere with its estimation, forming the complex sulphocyanides mentioned as newly-discovered compounds in a recent abstract in the Journal, while when mercury is also present a number of very curious reactions are obtained. It appears, nevertheless, that the tellurium is present in combination with gold. A number of fairly obvious inferences can be drawn from this, such as losses of gold during assaying, but I do not think that this is likely to be serious, unless local concentrations of the telluride occur somewhere, and I do not wish to exaggerate the importance of the tellurium.

Radium

It would be interesting to purify the uraninite by mechanical means—probably flotation would separate sulphides, arsenides and metals from the oxide—and ascertain the true constitution of the pure mineral and its radioactive value. Some samples of pitchblende have five times the activity of the radium contained, though the U: Ra ratio is constant. As the concentrate shown here contains approximately 142 milligrams of radium per ton, and the world's radium consumption is about 25 grams per annum, it would require about 200 tons of concentrate to supply the demand, presuming almost complete recovery. However, this is probably not a practical line. I only mention it as interesting statistics. Possibly another suggestion may be placed in a similar category— that our ventilation experts might consider placing a quantity of this concentrate in front of the ventilating fans and then determine the ionisation of the air in different parts of the mine to determine percentage air delivery to any given point. A preliminary survey of natural ionisation of the mine air due to radioactive matter in the rock would be necessary. An auto-photograph made by the uraninite in 24 hours is shown—the fainter initials at one side were made by thorium oxide recovered from an East Rand concentrate.

List of Constituents

The following is a list of elements which have so far been proved in reef and concentrate samples: Aluminium, antimony, arsenic, bismuth, calcium, carbon, cerium group, chromium, cobalt, copper, gold, hydrogen, iridium, iron, lead, magnesium, manganese, nickel, osmium, oxygen, palladium, phosphorus, platinum, potassium, radium, rhodium, ruthenium, silicon, silver, sodium, sulphur, tellurium, thorium, titanium, uranium, yttrium group, zinc, zirconium. I think that we can take as read some thirty-eight known radio-active substances, which we must presume to be present. But the gases helium, argon and nitrogen could safely be added to the list. Practically all these elements are present in quite appreciable quantities in some of the usual concentrates.

Rare Earths

It is interesting to know that some of the rare earths (thoria, ceria, etc.) occur in more than one mineral found in the reef. Sometimes very considerable amounts in acid-soluble form are found even in the absence of uraninite, and also there may be forms insoluble in any acids, but decomposed at a good red heat by fused bisulphate. The compounds of cobalt, nickel, arsenic, chromium, titanium, uranium and rare earths shown here have all been prepared from samples of concentrate received at various times from reduction works—their origin is their only novelty, but the quantities shown will impress you with their comparatively high concentration, as in each case the material was obtained from only one batch of material dissolved in the laboratory in the ordinary course for gold or osmiridium recovery.

Since writing the above, I have received an interesting specimen of "Millerite," or "Capillary Pyrites," taken from a cavity in the reef on the Far East Rand. This is practically pure nickel sulphide.

HOLDINGS IN SOUTH LORRAIN OF NEW RHODESIA MINES & INVESTMENT CO.

At the annual meeting of this company in London on November 30th, one of the directors. Colonel Ralph Cobbold, dealt at length with his impressions of mining in Canada, and in particular of the South Lorrain district, where the company had acquired interests. In the western portion of the district, which particularly interested the company, there existed probably the richest patch of ground in the world. From south to north there were the Lorrain Trout Lake Mining Co., the Keeley, the Frontier, the Belle Ellen (in which this company had an important interest), and the Taylor-Conkey areas. The Woods vein ran from the northern end of the Trout Lake to the north through the Lorrain, Trout Lake and Keeley properties, and then through a long line of properties owned by the Mining Corporation of Canada, for the best part of two miles to the north. This Woods vein was yielding high-grade silver ore in all properties that had been developed. The Belle Ellen claim lay east of the Woods Vein, approximately 200 yards from it; the general dip was east towards the Belle Ellen at an angle of about 65 degrees. The claims R. L. 455. and 456, in which also the company was interested, lay some 500 yards west of the Woods Vein or fracture. This fracture was broken by cross-fractures running east and west, in one of which (vein 26 in the Keeley property) phenomenal values were discovered last year. Vein 26, if it continued, would probably cross R. L. 455: it was heading in that direction. The discovery to which he had alluded was in a length of 74 ft., from which an average of 2,6000 ozs. was extracted over an average width of 15 ins.—over 250,000 ozs. of silver taken out without stoping. Colonel Cobbold went on to allude to the experience of other properties in the neighbourhood mentioned above, and their bearing upon the company's interests. There was no reason why, when the property developed in depth, highly satisfactory results should not be achieved. The surface veins on the Belle Ellen were perhaps stronger than any other surface veins in the district.

The property was pretty well equipped with compressor, with power ready to hand; a shaft was down from 250 ft. and everything was ready for active development. In his opinion South Lorrain was the great centre of interest in the mining world of Canada. It required only a question of time and a judicious expenditure of capital to enable their interests there to make good and ensure a prosperous future for the company.

DOMESTIC COKE FROM SYDNEY

A substantial increase in coke production at the steel plant in Sydney took place last week when the coking period was reduced, thereby giving a larger daily output. Formerly the ovens were operating on a 22-hour schedule, but now this time is reduced to an 18-hour schedule, for all three batteries. Under the new time, the former output, averaging 1,365 tons daily, will be increased to approximately 1,700 tons. The demand for domestic coke is good at present, and in order to supply the trade requirements it has been found necessary to secure a greater tonnage. No. 2 battery, which was recently put in operation, is now giving very satisfactory service, and will continue to improve from month to month. Whatever other departments of the steel plant may be affected this winter by industrial conditions, there is every indication that the coke ovens will be operated nearly to capacity.

CONSOLIDATED GOLD FIELDS OF SOUTH AFRICA IN ONTARIO

In the annual report issued in November of this company, which owns mines on the Rand, in Rhodesia and elsewhere, it is stated that, with a view to obtaining a footing on the ground floor in the Ontario gold territory, the directors have acquired a minority interest in the Porcupine Goldfields Development Company.

NITRATES FROM METHANE

A new process for recovering cyanide compounds from atmospheric nitrogen by using methane or its products of dissociation, has been patented in Germany.

Methane, as is well-known, at temperatures beyond 1,000 deg. C., splits up into carbon and hydrogen of extreme purity. If such carbon be mixed with barium carbonate or formed into briquettes with same, and these heated in a stream of nitrogen to 1,100 deg.-1,300 deg. C., then the nitrogen combines with the barium and the carbon to barium cyanide, from which, after reduction with potassium carbonate, a good yield of potassium cyanide is obtained, with barium carbonate again as a by-product. The latter is uncontaminated with slag and can at once be used to form cyanide.

The heat required for the process is supplied by the hydrogen from the methane, which, upon being burnt with the correct amount of air, yields a mixture of water vapour and nitrogen. Upon the gases of combustion being cooled, the water vapour is precipitated, leaving pure nitrogen behind, which can be used to produce the barium cyanide.

The process would form the basis of an atmospheric nitrogen industry wherever natural gas is available. - Abstract from Technische Blaetter, in Bulletin of the Cleveland Scientific and Technical Institution.

THE STORY OF ASBESTOS

The November and December issues of *Compressed Air Magazine* contain an unusually complete account, in non-technical language, of the asbestos industry of Quebec from the pen of Norman R. Fisher of Consolidated Asbestos. It is a distinct service to the industry thus to set before the general reader the facts about the mines and mills that contribute the larger part of Quebec's mineral production.

METAL MARKETS

(Prices in carload lots, f.o.b. Montreal, as quoted by Consolidated M. & S. Co.)

Average for week ending Dec. 18th

Electrolytic copper	15.00
Zinc	7.80
Lead	7.95

Bar Silver Prices

Average for week ending Dec. 14th

London	33⅛d.
New York	65½c.

THE MINING DISTRICTS

By THE JOURNAL'S CORRESPONDENTS

NORTHWESTERN QUEBEC

Coniagas Mines has a block of 12 claims, aggregating about 2,400 acres, under examination south of Pelletier Lake, in Rouyn township. They were led to examine the group by a promising find on the Spry claim, which is about the centre of the block. According to the present owners, Messrs. Gamble, Bathurst Hoffman et al., a schisted zone 175 to 300 feet wide has been located on the Spry claim. There are stated to be a number of parallel shearings in the Temiskaming conglomerate with intrusive porphyry. Quartz veins and veinlets, from an inch to seven feet in width, carry visible gold, galena, molybdenite, iron pyrite, arsenical pyrites and some undetermined minerals. The strike is approximately east-west, and the dip is 45 to 65 degrees to the north.

Coniagas makes no payments on its option until January, when $1,500 is due. The total consideration is $500,000, with no serious payments coming due for two years.

NORTHERN ONTARIO

Activity in Deloro Township.—Very interesting is the finding by M. J. O'Brien Limited of a gold-bearing vein in the first of a series of drill-holes now being put down on a group of claims in Deloro township, Porcupine. The O'Brien group adjoins March Gold, Ankerite and one of Goldale's several groups. About thirty feet of drill core has indicated a vein width of about 12 feet. Average values were better than $14 a ton. The vein section is in greenstone between two extensiv masses of porphyry that extend in an east-west direction through Deloro township.

Diamond-drilling is being carried on at the March Gold from the 800-foot level, and from the surface. A drifting and crosscutting on No. 1 vein at 800 feet has given low values across widths up to 98 feet.

Drilling is also being done at the Ankerite, and the adjoining Paymaster and United Mineral Lands group. A short distance to the west, on the Edwards property, English interests have installed a mining plant and shaft sinking is under way.

Porcupine. — Coniagas, operating Newray Mines, has changed over its mining plant from steam to electric power and will soon be sinking its shaft to 1,000 feet. The shaft is now at 400 feet. Electric power is being supplied by the Great Northern Power Company from its Indian Chutes plant.

Nighthawk.—Nighthawk Peninsular's mill is being gradually brought up to its capacity of 200 tons a day. It has been intimated by officials that a grade of $10 a ton or better will be maintained.

McIntyre Mine is now approaching Dome's production. Dome's output in November was $380,000 from $10 ore; McIntyre produced $350,000 from $11 ore. McIntyre runs 1,000 tons daily, Dome just under 1,300 tons daily. Dome's average ore content is down slightly, having been from $11 to $12 for a year past. This is due to the unusually large amount of rock from development going into the mill.

There is already a credible talk of enlarging McIntyre's mill, since good widths of ore of a good grade were encountered in several veins on the new low levels. Mill enlargement will come certainly, but the decision of the directorate will await the blocking out of ore in the levels from 1,875 to 2,500 feet. Not much of the material opened below 1,875 is included at present in ore reserves. McIntyre for years paid dividends almost entirely from one vein. Now it has six large veins capable of substantial production.

Kirkland. — Lebel Ore, Lebel Township, is drifting on the 200 foot level on the vein that gave high gold returns in the shaft at 160 feet. The west drift showed commercial grade for only a short distance, but the east drift, now in about 100 feet, has showed what the management describes as good ore.

Northland Gold Mines, owning a large block near the centre of Gauthier Township, east Kirkland district, plans to start shaft sinking shortly. An initial depth of 500 feet is being considered by the management. On this property during the past several months a steam driven plugger drill has been used to open up a number of vein outcrops. While the values found in these veins, eight in number, are not commercial, it is hoped that ore will be found at depth. A small mining plant is being installed.

Boston Creek.—Work on the 350-foot level of the Barry-Hollinger property, has been giving encouraging results recently, though these are not decisive. The schisted country rock adjacent to the gold-bearing quartz veins has been found to carry low values. This property was at one time a producer in a small way, being known as the Patricia.

Matachewan.—Officials of the Sterling Development Company, which has an option from Weldon C. Young on the Davidson property, Matachewan district, state that the first drill-hole has given satisfactory results. Nos. 2 and 3 drill holes are now under way. About 5,000 feet of drilling is contemplated. The Sterling Development company, which is a Toronto concern, turned over its option to the Porcupine Goldfields, an English company said to be backed by South African capital.

Cobalt.—One of the most interesting of recent developments at Cobalt has been the opening up of a shoot of high-grade ore in the Genesee Mine, north of the Chambers-Ferland group. Up to last week 125 feet of drifting showed good ore, from which twenty tons of high-grade has been sorted and bagged. This will probably average 1,000 ounces to the ton. In addition to high-grade, from two to three tons of screenings from the ore-sorting table have been made that averages well over 100 ounces to the ton.

Judging from results in the drift, and based on the expectation that the shoot will have a depth of 60 to 70 feet, the prospects are that a half million ounces will be mined from this shoot. There are several parallel veins still to be explored. The Genesee is controlled by a Rochester group and has been working since 1915. This is the first commercial ore found in the mine.

South Lorrain. — The engineers of the T. and N. O. Railway have placed in the hands of the Commission their report and plans for a branch railway connecting the mines of South Lorrain with the concentrators of Cobalt. The building of this line has not been ordered but it is confidently expected by some of those in close touch with the Ontario Government that construction will commence early next spring. Splendid deep level developments on the various Mining Corporation holdings should encourage this expenditure, especially in view of the fact that the railway would have good freight and passenger traffic from the beginning.

The silver-bearing horizon in South Lorrain has already been proved to be thicker than that of Cobalt, which latter camp has managed to produce $200,000,000 worth of silver from an horizon seldom more than 300 feet thick. Along the Woods fault vein, high-grade silver ore has been encountered over a length of a mile and a half, and for the southerly half of this length it is under intensive development. It is apparent that South Lorrain has several years of profitable life ahead of it. Developments outside the Woods fault, such as that of Canadian Lorrain on the Maidens Creek section, are expected to enlarge the producing area.

The railway from Cobalt would be 18 miles long, and would cost about $30,000 a mile. The engineers favor a route leaving the main line at Cassidy siding, about three miles south of Cobalt, and from there following the course of the Montreal River. This route of the three proposed, also is the one favored by the mine operators.

BRITISH COLUMBIA

Portland Canal. — The Granby Consolidated Mining & Smelting Co., will ship approximately 3,000 tons of ore from the Outsider Mine, Maple Bay, within a few weeks. H. S. Munro, general manager, says that these shipments will start before Christmas and that they will be doubled during the New Year. The concentrator, now under construction, will be finished within two months and the new dam, completed some time ago, is giving satisfaction. The Hidden Creek Mine reserves are sufficient to maintain operations on the present scale for from eight to ten years. From the standpoint of future operations, Mr. Munro is quoted as saying that there is more ahead of the Granby Co. at Copper Mountain than at Anyox. The Granby Co. holds title to timber limits containing from 400,000,000 to 500,000,000 feet of timber, of which some 40,000,000 feet on the Kitsault River, according to government report, is being smoke killed. This timber is to be cut immediately and shipped to the Orient, most of it going to Japan.

Kimberley. — Hon. Frank Carvell, chairman; Hon. Frank Oliver, and other members of the Railway Board of Canada, inspected the Sullivan mine, and the Kimberley concentrator of the Consolidated Mining and Smelting Co., early in December. Another recent visitor at Kimberley was Frank M. Smith, smelter director of the Bunker Hill and Sullivan Mining and Concentrating Co. He was accompanied by Livingston Wernecke, manager of the Treadwell-Yukon Co., operating the silver-lead mines in the Yukon from which 4,000 tons of high-grade silver-lead ore was shipped to the Bunker Hill smelter last summer.

Rossland.—It is reported that the last shipment from the I. X. L. Mine was the richest yet made from that property. On the adjoining group, the O. K., the lesses are reported to be working on a quartz vein that is widening steadily and it is their confident expectation that they will strike rich free-milling ore before long.

Nelson.—The Lucky Jim Mine, Zincton, is reported sold to A. G. Larson and associates, the deal having been negotiated through the Canadian Bank of Commerce at Nelson. Acting as trustee appointed by the Courts, Mr. Larson paid off the first mortgage, sums due the unsecured creditors, and a further substantial payment on the second mortgage. These moneys, it is stated, all were raised out of the proceeds of ore taken from the mine and shipped to the smelter. Mr. Larson proposes extensive development as soon as weather permits. There is no mill on the property, but water power, a compressor, and other equipment are available.

Road Recommended. — George Clothier Resident Government Engineer for the Northern Division, announces his intention of making representations to the Alaska Road Commission with a view to arranging for the co-operative construction of a trail up the Unuk River from tidewater to the head of the river, with branch trails up its two principal tributary creeks, in all totalling about 40 miles, about half of which would be in Alaska. This would open up a promising mineral bearing zone.

Hedley.—The Hedley Gold Mining Co. has sunk a a 100-foot shaft during the past year. The mine now is closed down, but diamond-drilling and repairs to the mill are under way.

Allenby.—At Copper Mountain, recently taken over by the Granby Company, extensive diamond-drilling between known ore bodies has been in progress during the summer. The mine has been put in shape for operation, the mill at Allenby altered and dry crushing machinery housed separately, a new flotation unit installed, and arrangements made to take care of tailings. The railway grade has been cleared. The mine now awaits only a rise in the price of copper to go into profitable operation.

Atlin.—In Atlin district, northern British Columbia, a lode prospect has been opened up on Fourth of July Creek by J. M. Ruffner which is promising. The Engineer Mine has been idle durng the year and, as further litigation is pending, it is not likely to be operated in the immediate future. The placer gold yield for the season, it is estimated, will be 9,000 ozs. and it is becoming apparent that the placer production will gradually diminish with the depletion of the smaller creeks.

SILVER RESEARCH AUTHORIZED

Secretary Work of the Interior Department has authorized the United States Bureau of Mines to initiate its proposed research into possible new uses for silver in commerce and industry and made temporary provision for the work through the release of a portion of the reserve funds within his charge.

The Transvaal gold output for October 1923 amounted to 793,842 fine ounces, as compared with 739,504 fine ounces for September 1923, and 778,169 fine ounces for October 1922.

NOVA SCOTIA

Steel Plant Slowing Down. — The usual seasonal slowing down has taken place at the Steel Works, New Glasgow. The 15-inch mill has been temporarily closed down and the bar mill will also be closed shortly. Eight of the twelve steel producing furnaces are now in operation. Other departments are fairly well employed. Mr. Bischoff, General Superintendent of the steel plant states that at present the Company have few orders on their books, as the steel industry has slumped both in Canada and in the United States; but a general improvement is expected after the New Year. Rail orders are expected from the Canadian National Railways, which may keep the Sydney steel workers steadily employed throughout the winter.

Domestic Coke Sales Growing. — It is stated that the coke department, Sydney, will be busy during the winter on domestic coke, as the demand is growing rapidly. This is good news, as it will provide at least one steady department through specialized effort along new lines. Householders must have fuel under all conditions, and coke is the best fuel available.

Idle Time at Collieries. — There is considerable unemployment at the collieries. It may continue for some time; but we are not alone in this respect. Mr. Andrew Steele, International Board Member, District No. 26, representing President Lewis at the wage conference now going on, states that coal conditions in the United States, owing to mild weather and accumulated coal supplies, are not promising. Many of the largest mines are shut down, throwing thousands of men out of employment. This condition is not peculiar to the American continent just now, for Britain and other European countries are all suffering alike.

An Appeal to Government. — The following appeal has been made to the Premier Mackenzie King by Silby Barrett, President of District No. 26, United Mine Workers. Other resolutions of a similar nature were passed and forwarded to the Government by the different Locals.

"Hon. W. L. Mackenzie King, Premier of Canada, Ottawa.

"I beg to place before you the matter of the unemployment at Nos. 2, 4, and 6 collieries in the Glace Bay district; No. 3, Jubilee and the Princess at Sydney Mines, and No. 16 colliery at New Waterford. All those mines are working only two days per week, and at some weeks, no time at all is worked. Those mines employ about 4,600 men; most of them have large families depending upon them. Those families are in destitute circumstances, and it is our opinion that the government of Canada should make arrangements to take coal from these mines, so as to relieve the unemployment situation, instead of buying coal from the non-union coal operators in the United States. These men are entitled to a living for themselves and their families, and it is the duty of the government which is now administering the affairs of the country, to see that something is done to relieve the present situation.

"The Government of this country advocates that the Canadian people buy Canadian made goods, but they do not set this example themselves, for they buy coal from the non-union coal operators of the United States, who are doing more to destroy organized labor, and who are greater tyrants than the German Kaiser, of the Czar of all the Russias ever dared to be. We hope your government will give this matter your earnest consideration, and would request an immediate reply.

(Signed) SILBY BARRETT,
Provisional President,
U. M. W. of A.

Ill-Advised Arguments. — While all are in sympathy with the unemployed at the collieries, we rather think the appeal is weakened by the suggested remedy and the protest against non-union coal operators. Were any one of us placed in the position of Sir Henry Thornton, if we possessed business acumen we would sit down first and count the cost, and then would buy to the best advantage. The whole country is looking to him to put the railways on a paying basis, and he has said it can and will be done. In the meantime, until it is done each citizen of Canada has to pay his share of the yearly deficit in taxes. President Barrett would add to these by un business like methods, for just at the very time when he is appealing to the Government for aid, he is trying to put a wage agreement through that will, if granted, further increase the price of Canadian coal.

Unemployment a Result of the Strike. — Another resolution pointing out that one colliery only worked two hundred and four days up to the sixth of December and only forty-four days in the last three months was forwarded to the Government. If the senders of thse resolutions only stopped to consider the case they would see the ridiculous position they place themselves in before the public, for the foolish July strike is not forgotten and it is well known that because of this strike a contract of over 400,000 tons of coal had to be cancelled, causing a loss of about forty-five full days' work at the collieries, which would have provided steady employment now.

Unemployment at Wabana. — A strong effort is being made to induce the B. E. S. Corporation to provide more employment for the workers in the iron ore mines at Wabana. Four mines are closed and two-thirds of the miners are idle, at a time when alternative employment is difficult to find. Appeals are being made by the government of Newfoundland to Mr. R. M. Wolvin to adopt some means that will give some measure of relief to the large number of men now out of work.

Safety Device Installed. — Lilly Controllers or safety devices to prevent overwinds or run-away cages in shafts are being installed at all the collieries of the B. E. S. Corporation operated through shafts. The device is said to be perfect in action and arrests the flight of a cage without creating another danger just as serious as the one it is supposed to correct. There is no sudden stopping of a cage, but a very gradual slowing up, except at the mouth and the bottom of the shaft. When the cage exceeds a certain speed there are certain mechanisms that begin to spread and that keep spreading until the effect is felt at the throttle, which is closed while at the same time the brakes are put on. In mid-shaft, action is slow, for here the speed of the cage is greatest and the cage must be brought to a standstill very slowly; but at either end, action is rapid. The device is electrically operated, a strong magnet being used, which puts the controllers in motion.

THE SULPHUR AGREEMENT

The present international agreement regulating the sale of sulphur is described briefly and succinctly in a recent report by the United States Geological Survey, thus:

An agreement between the American and Sicilian sulphur producers regulating the world's sulphur market was consummated early in the spring of 1923. The agreement, which applies only to unrefined sulphur, was to hold until September 30, 1923, thereafter to be renewed. The prices will be regulated in relation to the demands for consumption, with an intention of gradually regaining the pre-war levels based on a gold standard, and will be increased by $1 a ton over those temporarily put into effect in October 1922. North America will be supplied by the American producers, Italy by the Sicilian producers, and the remainder of the world proportionately by the two groups, with the provision that Sicilian producers may sell to any country a maximum of 65,000 tons for the manufacture of sulphuric acid. This agreement permits Sicily to export annually 210,000 tons, including 65,000 tons for sulphuric acid, a quantity largely in excess of Sicilian exports in recent years. A central bureau will be established in London to exchange information and statistics between the contracting parties to facilitate the execution of the agreement. The contracting parties are obliged to maintain the present status of the industry so far as the refining and grinding of sulphur is concerned, a provision which amounts to a guaranty of market for the Italian output of worked sulphur. Disagreements arising between the contracting parties will be submitted to a London board of arbitrators composed of a representative of each party and a third agreed upon by these two or in the event of failure to agree by the president of the chamber of commerce. The agreement may be terminated at any time prior to 1926 on not less than six months' notice, except during the sulphur-selling season.

The Texas Gulf Sulphur Co., as part of its contribution to the solution of the problem of finding a market for sulphur, has established a scientific-research department for the purpose of determining new uses for sulphur and increasing consumption.

RESEARCH INTO TRANSPORTATION PROBLEMS

The National Transportation Institute with headquarters in Chicago, has been formed to bring together into a single unit the various transportation units of the United States. In the by-laws it is stated that the object of the National Transportation Institute shall be to conduct non-partisan and impartial investigations and research into every kind of transportation and the relationship of transportation agencies to each other and to Agriculture, Industry, Finance and Commerce and to disseminate the facts thus acquired to the public through the platform, press, educational institutions, motion pictures, and other available mediums, with a definite object of aiding the people of the United States in promoting, co-ordinating and maintaining the most efficient transportation facilities. The Institute shall not in any way become directly or indirectly the representative either of transportation agencies, producers, shippers, or of any special group or groups.

One of the principal activities of the Institute is in the direction of research. It has appointed a research council, and has employed a director of research and staff.

Let Hercules Oil Increase Your Profits

Steam-distilled pine oil is conceded to be the best flotation frother known. Moreover, it is the cheapest flotation reagent in the long run because it recovers the greatest amount of concentrate per ton of ore.

This fact has found favor for Hercules Pine Oil with many flotation operators and engineers.

Hercules Pine Oils are produced under strict chemical control. The grade of oil which best meets your needs having been determined, we can supply that grade in uniform shipments.

We invite correspondence and offer the services of our technical staff in helping you solve your flotation problems.

"Sullivanize" Your Drill Steel

Sullivan Sharpeners and Steel Heating Furnace

DON'T handicap your rock drills or delay your runners by using steel that is improperly heat-treated, badly formed or poorly sharpened. Train your Blacksmith to put as much footage as possible into each steel he on the job.

Sullivan Furnaces and Sharpeners Provide Drill Steel Quality Insurance

The *Sullivan oil or gas Furnace* heats the steel gradually, evenly, while electrical devices prevent overheating or burning, and indicate, also if the steel is not hot enough for working or tempering.

The hammer-forging action of the Sullivan Sharpener refines the grain of the metal, and with each repeated sharpening renders it tougher, less liable to wear or breakage. Sullivan-sharpened bits are made to exact shape and gauge by tool steel dies and dollies. They "follow" accurately in the drill hole.

With the Sullivan gauging device, genuine double taper bits are quickly and correctly formed, providing increased drilling speed.

Sullivan Furnaces and Sharpeners insure that each steel is of uniform hardness, of exact shape, that the steel quality you paid is preserved and that you will obtain the maximum feet of hole from each steel.

Sharpeners, Bulletin 672-E

Furnaces, Bulletin 674-A

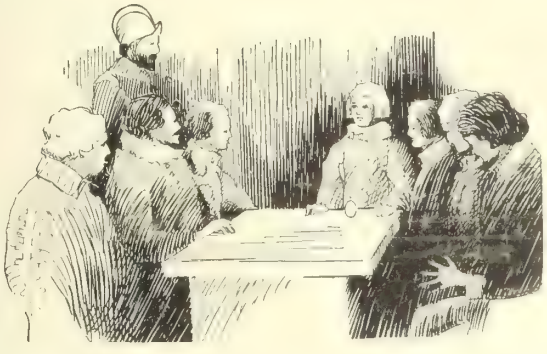
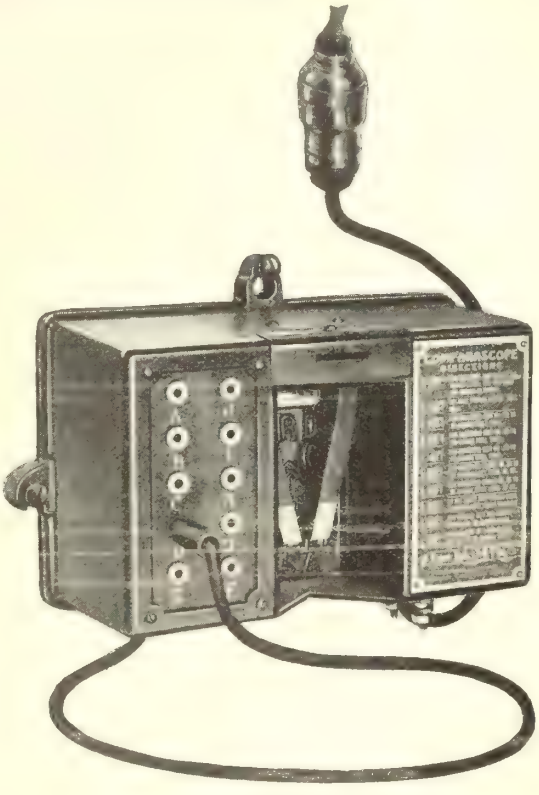
Simplifying Science





THERE'S a lot of finesse about the scientific heat-treatment of drill steel which nobody but a technically educated steel expert can be expected to master and apply.

BUT the inexpensive new Waugh Comparascope has so simplified the science of this art that perfectly heat-treated drill steel is now within the immediate reach of every blacksmith, without preliminary technical training.

HERE, at last, is a practical and completely satisfactory solution of the heat-treatment problem which means so much to the efficiency of every mine, both above and below ground.

Write today for a copy of the Comparascope bulletin which describes its operation in detail.

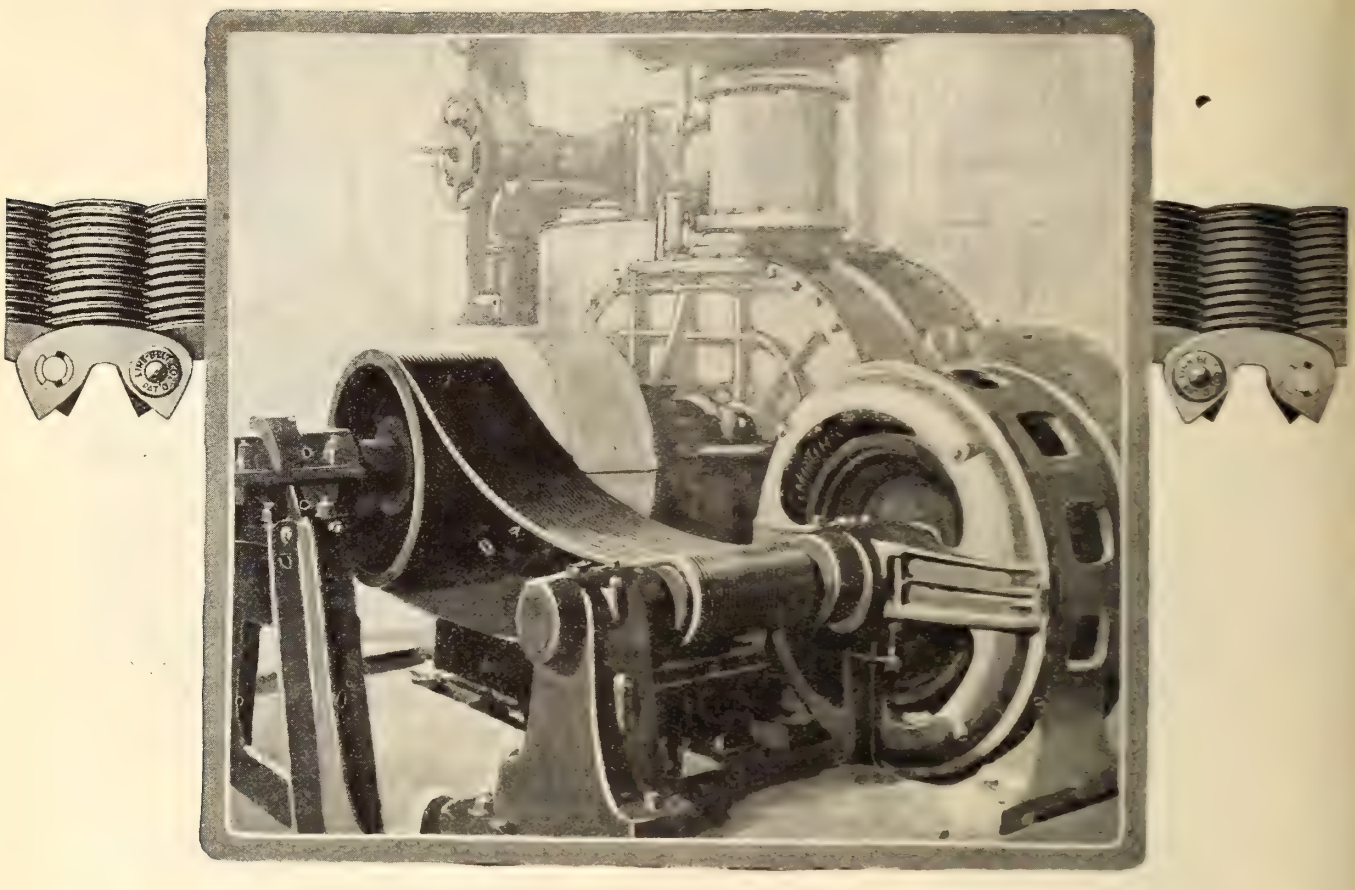
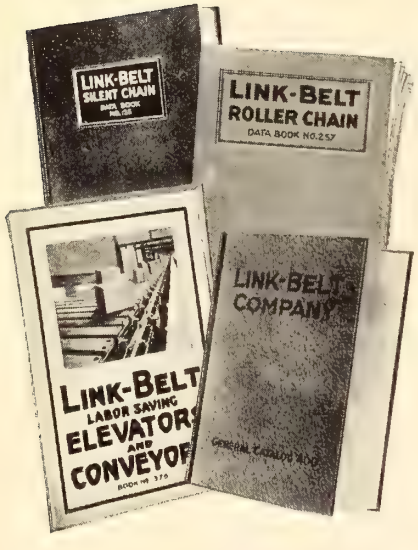
Rock Drills, Drill Steel Sharpeners and Hole Punchers, Portable Hoists





You can do much to inform yourself on elevating, conveying and power transmission methods and equipment by reading these books. Sent gratis on request.

Chain the Motor to the Machine

DON'T waste power—

Drive your machine and line-shafting with this 98.2% efficient Link-Belt Silent Chain Drive.

It is flexible as a belt—positive as a gear—more efficient than either.

It has earned an enviable reputation as the "Ideal" Drive in all lines of power transmission. And when enclosed in our patented oil-retaining, dust-proof casing it makes a real "safety-first" factory drive for machine tools, pumps, blowers, compressors; in fact, for every type of machine.

We sell each drive complete, and guarantee its performance.

Let our experienced power transmission engineers show you how to use this compact and efficient drive in your work.

The books illustrated will give those interested a good idea of the entire Link-Belt line of chains and elevating and conveying machinery. Copies sent on request.

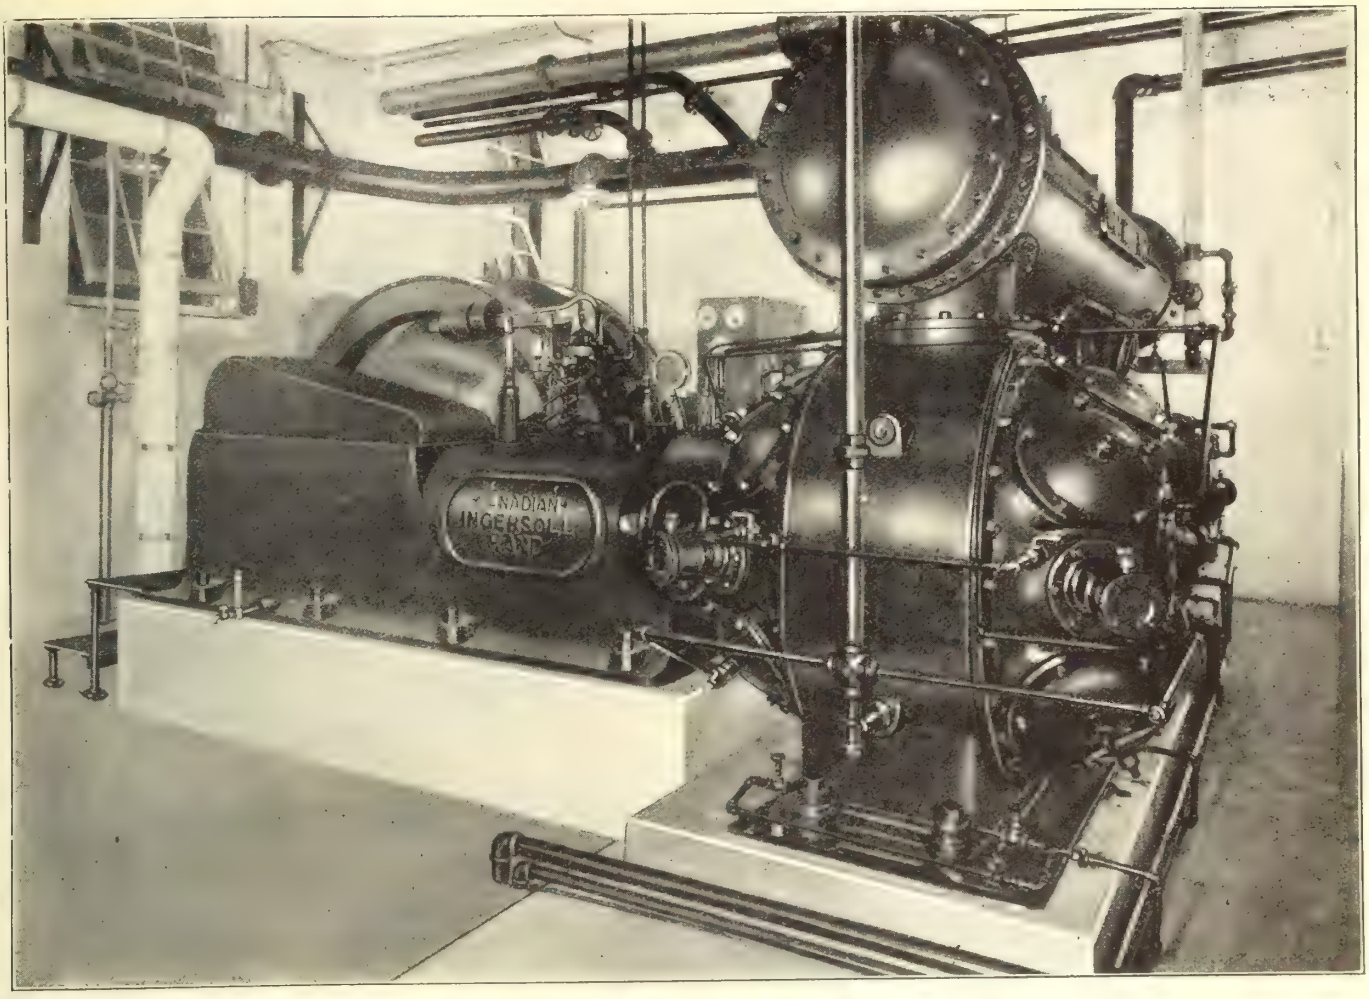
LINK-BELT
SILENT CHAIN DRIVES



At Westinghouse—

Few people have had a better opportunity to judge the value of motor-driven compressors in general than the large electrical concerns on this continent who have advocated the use of this type for many years.

That most of these firms have installed Ingersoll-Rand Class "PRE" Compressors in their own shops in the first place, or to replace machines of older types indicates the high esteem in which they are held.

To meet the increased demand for air at its Hamilton Plant, the Canadian Westinghouse Company recently sold its Ingersoll-Rand steam driven unit to an Eastern Coal Co., and installed the 18" stroke Class PRE-2 unit shown above. This machine is direct-connected to a Westinghouse 355 h.p. 2200 volt, 66 cycle, two phase, 200 r.p.m. synchronous motor and supplies air to a host of air-operated appliances used throughout the works.

The Automatic Five-Step Clearance Control with which this machine is equipped permits operation at full, three-quarter, one-half, one-quarter and no load with corresponding reductions in power consumption.

Many mines, industrial concerns, railroad shops, etc., who have cheap hydro-electric power available, are replacing their older types of compressors with these up-to-date units which provide closer regulation and better efficiencies than any other type.

Bulletin K 317 just off the press describes "PRE" compressors in detail. Write for a copy.

Ontario's Minerals

PROVINCE OF ONTARIO

Hon. CHARLES. McCREA, Minister. DEPARTMENT OF MINES *Thos. W. Gibson*

Mineral Areas

Ontario, with its 407,262 square miles, contains many millions of acres in which the geological formations are favourable for the occurrence of minerals 70 per cent of the area being underlain by rocks of pre-Cambrian age. The phenomenally rich silver veins of Cobalt, Gowganda and South Lorrain occur in these rocks; so also do the far-famed nickel copper deposits of Sudbury, the gold of Porcupine and Kirkland Lake, and the iron ore of Magpie and Moose Mountain mines.

Economic Minerals

In addition to the above, practically all economic minerals (coal and tin excepted) are found in Ontario: — actinolite, apatite, arsenic, asbestos, cobalt, corundum, feldspar, fluorspar, graphite, gypsum, iron pyrites, lead, mica, molybdenite, natural gas, palladium, petroleum, platinum, quartz, salt, talc and zinc. This Province has the largest deposits on the continent of talc, feldspar, mica and graphite.

Building materials, such as ornamental marble, limestone, sandstone, granite, trap, sand and gravel, lime, Portland cement, brick and tile, meet every demand.

Mineral Production

Preliminary returns show the output of the mines and metallurgical works of the Province for the year 1922 to be worth $62,202,169, of which the metallic production was $38,190,711.

The following figures show the growth of Ontario's mineral industry by five-year periods since 1891 when a Bureau of Mines was first established.

Year.	Value.	Year.	Value.
1891	$4,705,672	1911	$41,976,797
1896	5,235,003	1916	65,303,822
1901	11,831,086	1918 (Maximum war output)	80,308,972
1906	22,388,383	1921	48,128,387
	Dividends.		

Dividends and bonuses paid to the end of 1922 amounted to $28,096,699 for gold mining companies, and $86,238,185 for silver mining companies or a total of $114,334,884.

Mining Regulations

A miner's license costs $5.00 per annum, and entitles the holder to stake out in any or every mining division three claims of 40 acres each. After performing 200 days' assessment work on a claim, patent may be obtained from the Crown on payment of $2.50 or $3.00 per acre, depending on location in unsurveyed or surveyed territory.

Assay Office

The Provincial Assays Office at No. 5 Queen's Park, Toronto, is maintained by the Department of Mines for the free identification of minerals, free assays under the provisions of the Mining Act of Ontario, and also for general assay work as per the Schedule of Charges which may be obtained on application.

Temiskaming Testing Laboratories

The Department maintains, at Cobalt, an ore sampling and testing laboratory which is now prepared to receive parcels of gold ore from 100 pounds upward, and after sampling and assaying the same to pay to the shipper the value thereof, less treatment charges. The purpose is to afford a market for ores extracted by prospectors and others in developing their mining claims, enabling them to obtain funds which they can use for further work and to report on the most satisfactory method of treatment. Fuller information may be obtained on application to the Manager, Temiskaming Testing Laboratories, Cobalt, Ontario.

BRITISH COLUMBIA

The Mineral Province of Western Canada

Has produced Minerals valued as follows: Placer Gold, $76,542,203; Lode Gold, $109,647,661; Silver, $59,814,266; Lead, $51,810,891; Copper, $170,723,242; Zinc, $24,625,853; Coal and Coke, $238,289,565; Building Stone, Brick Cement, etc., $36,605,942; Miscellaneous Minerals, $1,358,839; Making its mineral production to the end of 1922 show an

Aggregate Value of $769,418,462

The substantial progress of the Mining Industry of this Province is strikingly exhibited in the following figures, which show the value of production for successive five-year periods: For all years to 1895, inclusive $94,547,241; for five years, 1896-1900, $57,607,967; for five years, 1901-1905, $96,509,968; for five years, 1906-1910, $125,534,474; for five years, 1911-1915, $142,072,603; for 5 years, 1915-1920, $189,922,725; 1921, $28,066,641; for the year 1922, $35,158,843.

Production During last ten years, $339,280,940

Lode-mining has only been in progress for about twenty-five years, and not 20 per cent. of the Province has been even prospected; 300,000 square miles of unexplored mineral bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than those of any other Province in the Dominion, or any Colony in the British Empire.

Mineral locations are granted to discoverers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full information, together with Mining Reports and Maps, may be obtained gratis by addressing.

VICTORIA, British Columbia

THE HON. THE MINISTER OF MINES

PROVINCE OF QUEBEC

MINES BRANCH

Department of Colonization, Mines and Fisheries

The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, etc.

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

MINER'S CERTIFICATES. First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. The price of this certificate is $10 and is valid until the first of January following. This certificate gives the right to prospect on public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres.

WORKING CONDITIONS. During the first six months following the staking of the claim, work on it must be performed to the extent of at least twenty-five days of eight hours.

SIX MONTHS AFTER STAKING. At the expiration of six months from the date of the staking, the prospector, to retain his rights, must take out a mining license.

MINING LICENSE. The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cents an acre per year, and a fee of $10.00 on issue. It is valid for one year and is renewable on the same terms, on producing an affidavit that during the year work has been performed to the extent of at least twenty-five days' labour on each forty acres.

MINING CONCESSION. Notwithstanding the above, a mining concession may be acquired at any time at the rate of $5 an acre for SUPERIOR METALS, and $3 an acre for INFERIOR MINERALS.

The attention of prospectors is especially called to the territory in the North-Western part of the Province of Quebec north of the height of land, where important mineralized belts are known to exist.

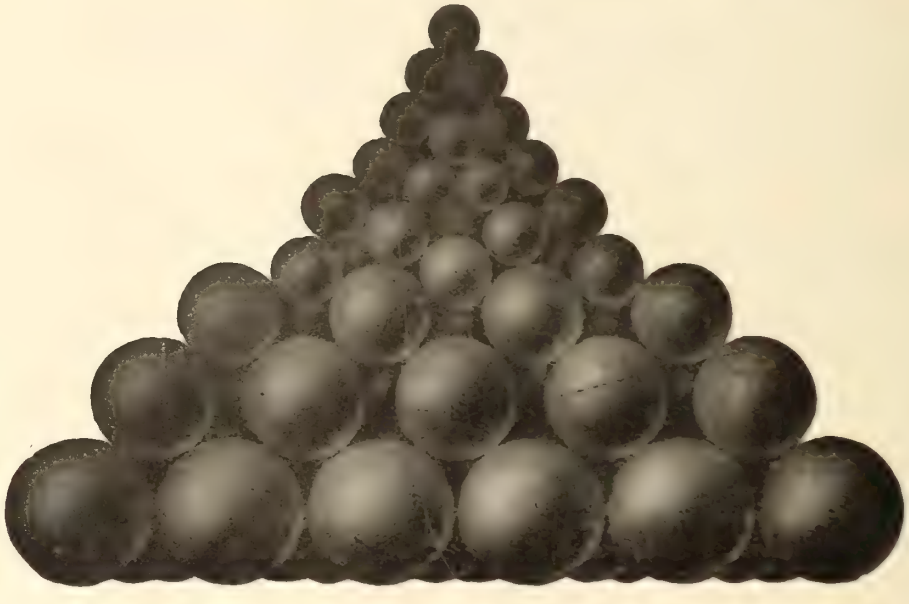
PROVINCIAL LABORATORY. Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY, 228 ST. DENIS STREET, Montreal, for the determination, assays and analyses of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensure results of undoubted integrity and reliability.

The bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of the Province, on application addressed to

HONORABLE J. E. PERRAULT,

MINISTER OF COLONIZATION, MINES AND FISHERIES, QUEBEC

Decrease your grinding costs.



USE HISCO BALLS

"If quality counts use 'Hisco' Products" *Hisco Balls* are noted for superior quality. They are in use in the largest ore and cement mills from Halifax to Vancouver. Forged from Electric Furnace chrome steel, absolutely the best ball on the market.

Sizes 3, 4, 5 and 6 inch carried in stock.
Special sizes from 6 inch up made to order.

Adding Impetus To The Development of Mining

The development of Canada's enormous natural resources will affect her whole future. Her vast mineral wealth, as yet practically untouched, is to-day attracting world-wide interest from far-seeing investors.

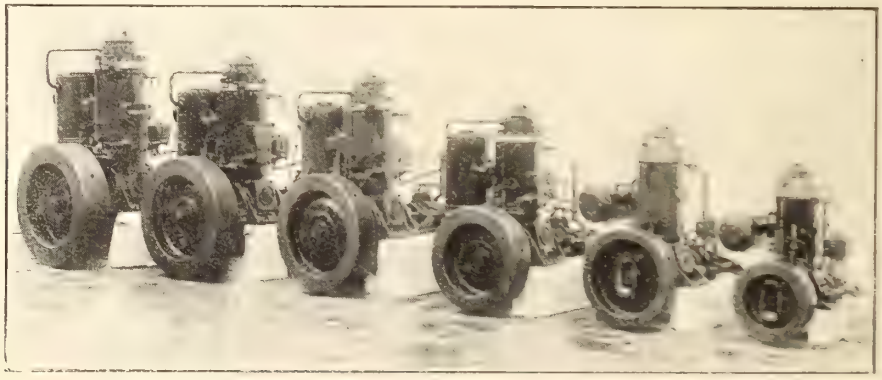
It is appropriate that the Imperial Bank, whose policy has ever been to concentrate exclusively on Canadian affairs, should be powerfully furthering that interest. This Bank, by placing branches at strategic points throughout the mining districts, has materially aided the whole industry.

Those who contemplate becoming connected in any capacity with mining would be well advised to take advantage of this Bank's facilities.

IMPERIAL BANK OF CANADA

Peleg Howland, President. A. E. Phipps, General Manager

The orders for KROMHOUT OIL ENGINES received during the last quarter have exceeded any previous period of three months since the engine was placed on the market over twenty years ago.



Various sizes of engines, single cylinder models 9 to 50 BHP

The KROMHOUT is of the 2 CYCLE SEMI-DIESEL type and is made in the following sizes

9 - 15 - 22 - 30 - 40 - 44 - 50

60 - 80 - 100 - 150 - 200 - 275 - 350 - & 500 BHP

It is adapted for either direct or beltdrive and is suitable for driving Pumps, Winches, Compressors, Crushers, & Electric light & Power generators, and in fact for all industrial purposes-

PLACERS IN COBALT CONGLOMERATE

During the eons of time that elapsed between the end of the great Laurentian igneous intrusions and the long Huronian period of deposition, the present peneplain of northern Ontario and Quebec was a surface of jagged mountain ranges, composed of rocks of the Keewatin, Timiskamian and Laurentian series. Erosion was probably more rapid in those days of barren hillsides and precipitate rains, and the enormous amounts of material represented by the beds of conglomerate, quartzite, sandstone, slate and limestone of the Huronian and similar series required less time to accumulate from the débris washed down from these mountains than would be the case under present conditions. The planet was, in all likelihood, without life; even the primordial slime in which the human species had its lowly origin could hardly have existed in the turbulent and impure waters that scoured the hillsides and rushed precipitately into seas on whose beds and margins they dropped their load of silt, sand and gravel. Nevertheless conditions were, in a geologic sense, much the same as they are today.

These mountains of Huronian times were gold-bearing. The wide-spread deposition, (and occasional concentration) of gold that followed the Laurentian intrusions had resulted in auriferous veins and zones, deep buried in the bowels of the hills. At first, none of these were exposed at the surface, but gradually erosion brought them to light, and eventually towards the close of Huronian times, they were exposed much as they are today. Subsequent periods of erosion, such as that which swept away a good deal of the Huronian series before Ordovician times, and the more recent period that was ended with the scouring and polishing of the glaciers, have not had the same profound effect on the topography as that of the great Huronian interval. The peneplain at the end of Huronian times was substantially the peneplain of today.

Gold placers were, doubtless, formed in Huronian times much as they have been during recent times. What a marvellous opportunity there was for the accumulation of the precious metal! Here was an area at least two hundred miles long and forty wide in which nature had stored a fabulous quantity of gold. Even the little outcrops of rock we can see today above the mantle of clay contain concentrations of gold that have already attracted world-wide attention, and this is the merest fraction of what is diffused in unpayable quantities. Within the area of eight thousand square miles there was eventually, we can safely assume, the concentrated wealth of many Klondykes—but no Klondykers to win it.

The question of present moment is whether any of these placers of primitive times can be found today. We believe there is at least a fighting chance. The gravel beds in which they were formed are now conglomerate in the Huronian series. The usual place for the accumulation of placers is on or near bed-rock beneath a bed of gravel. The contact of the basal conglomerate and the old rock surface upon which it accumulated is exposed in numerous places on the southern margin of the gold belt. Round Shining Tree there are some remnants of the Cobalt series, as well as an edge of the great sedimentary area that extends eastward. For twenty miles both east and west of Matachewan there are similar areas where the Keewatin-Cobalt contact may be found. From Englehart northeastward to Larder, and then eastward for twenty miles to the border of Rouyn township, there is another remnant of the Cobalt series resting on the gold-bearing Keewatin and Timiskamian rocks. In any or all of these localities it is possible that consolidated placers may be found in the basal conglomerate.

Up to the present there has been little or no search for these old-time placers; the idea that they may exist and may likewise be found has remained the exclusive property of a few geologists. The idea is worth spreading abroad. It would not be surprising to find, eventually, that the bottom edge of the Cobalt series in the areas mentioned is just as good prospecting ground, on the average, as the adjacent areas of Keewatin and Timiskamian rocks. We should like to have the views on this point of others who have studied the question.

ROADS TO ROUYN

On another page we record the measures taken to ensure the easiest possible access to the gold-field of northwestern Quebec from the south, during both the present winter and the coming summer. The provincial government at Quebec and the Canadian Pacific Railway both realize the potential importance of the present gold development, accompanied as it is by lumbering [illegible] with the large area of excellent agricultural land as the

greatest asset of all, though it will be more slowly developed. Meantime the Temiskaming and Northern Ontario Railway surveyors (or the Nipissing Central, more strictly speaking, for it is under its federal charter the work is being done) is pushing forward its survey eastward along the gold belt from Larder Lake. A road gang is busy on the winter road from Larder to Lake Opasatika, making detours round the worst of the hills and effecting general improvements. The interest in the Quebec gold development on the Ontario side is also reflected in the increased activity in the construction of the Swastika-Kirkland-Larder branch line of railway. A few weeks ago it seemed settled that this line would not be open for traffic until midsummer of 1924. Judging by the activity now to be seen, it will be ready by next spring.

BUREAU OF STEEL MANUFACTURERS

Australia has got another lap ahead of Canada in building up her iron and steel trade. Nature has been good to our sister Dominion, and has provided in abundance the raw materials required for a large iron and steel industry. A number of plants have been erected during recent years, and most of them have been successful, in spite of acute labour troubles. Now success is made still more certain by the inauguration of a Bureau of Steel Manufacturers, whose stated object it is to forward the common interests of all its members.

The new Bureau's organization and proposal activities are not merely experimental. They are along the lines of similar bureaus or federations that have helped British manufacturers so much during recent years. The separate companies have much to gain and can lose little by entering such an association.

Periodically we have pointed in these pages to the fact that the iron and steel industry in Canada has no central organization. Its units, large and small, have no means of organizing or conducting a plan of concerted action, outside of the Canadian Manufacturers' Association, whose interests are far too broad to serve the purpose. Each unit of the industry goes its own way, mainly irrespective of the rest. Questions that affect the whole industry are either left in abeyance or are tackled piece-meal, with the result that little is accomplished.

If ever there was a country that needed a well organized iron and steel industry, it is Canada. The problems confronting the industry are of prime importance and are pressing; they need not be recounted here. The advantages of concerted action to solve these problems are obvious. The effectiveness of combined effort has been shown so often that it does not need added proof.

Though the interests of our various iron and steel plants are not identical throughout, there are a number of rallying points round which they can gather. The sooner they get together to study and attack their common problems, the better will they be able to cope with the peculiar difficulties that will always beset the manufacture of iron and steel in Canada.

THE LARGEST GOLD MINES

Today we print some items from the annual report of the New Modderfontein in South Africa, the fourth largest gold mine in the world, which affords an interesting comparison with the Canadian champion, Hollinger, which is third in point of production. Crown Mines stands first, and Government Gold Mining Areas, second, the outputs for 1922 being:

	Ounces
Crown Mines	602,960
Government G. M. Areas	600,954
Hollinger	590,385
New Modderfontein	474,945

For 1923 the order will probably remain the same. At the end of next year, however, we shall probably see Hollinger well in the lead. The world's record is another matter. In 1913 Crown Mines produced 772,193 ounces. It will probably require an additional year for Hollinger to match that output.

THE PROGRESS OF CONSOLIDATED

During the past year prices of Consolidated's chief products, the base metals, have not been high and recently have declined. It is, therefore, highly satisfactory to note that the directors have been able to announce a 6 per cent. dividend for the year 1923. Only the excellent sources of ore available, notably at the Sullivan mine, and the superior technology of the concentrating, smelting and refining processes have made this possible.

With the announcement of the dividend has come the following official statement:

"While the results of the year's operations might warrant a larger dividend, the directors think that it is in the best interests of shareholders to strengthen the treasury rather than make too generous a distribution of profits. Moreover, increased production calls for additional working capital.

"The new mill at the Sullivan Mine is working quite satisfactorily. Current Smelter production of lead and zinc combined is exceeding 7,000 tons per month. Silver production is about 250,000 ounces per month.

"A start has been made on milling Rossland ores—some 400 tons being treated daily. It will be some months before anything really definite can be said as to the future of the Rossland properties.

"The plants and mines are in good condition.

"Satisfactory progress is being made by the West Kootenay Power Company in the development of additional hydraulic and electrical energy at Bonnington Falls."

TRAIN AND BOAT SERVICE TO QUEBEC GOLD-FIELD NOW ARRANGED

The activities of lumbermen, pulp and paper companies, prospectors and mine operators in the counties of Temiscamingue and Abitibi, Quebec, served by the new railhead of the Canadian Pacific Railway, at Angliers on the Quinze river, is such that transportation facilities for both summer and winter travel have now been organized from that centre. The provincial government have announced their attention of establishing at Angliers an assay office to be operated by J. T. Donald and Co. of Montreal, and it is probable that the mining recorder's office now located at Ville Marie will be moved to the railhead. The new winter road from Angliers northward to the gold district will soon be in commission.

It is now announced that a suitable freight and passenger train service to meet the requirements will be established on the new line of the Canadian Pacific Railway as soon as the necessary formalities of its inspection and approval by the federal and provincial authorities have been completed. This will serve adequately those who will use the new winter road northward, which will join the present east-west road along the gold belt at or near Lake Olier. It has been decided by the provincial government to construct a summer road from the head of Lake Opasatika eastward to the gold properties in Rouyn township, commencing next spring.

To take care of the summer travel up to the head of Lake Opasatika, whence the last mentioned road will extend into the prospective mining area, arrangements are being made for a regular motor-boat service operating in conjunction with the railway. Passengers and freight arriving by rail at Angliers will be transferred to motorboats on the lower system of lakes. A feature of this boat service will be the construction of a tramway portage at the Barrière portage, on which it will be possible to transfer the passengers and freight from the boats on the lower lakes to a connecting boat service to be operated on the upper waterway. The construction of this tramway portage is to be undertaken at once.

The provincial government has appropriated $200,000 for the building of the summer and winter roads, contracts for the boat service are being arranged, and a train service from and to the south will be inaugurated as soon as government action permits.

MINING MEETING AT NELSON

The annual meeting of the Mining Association of Eastern British Columbia was held recently at Nelson. There was a large attendance and the proceedings were notable for some announcements of first-rate importance to the mining industry of the Province.

It was stated that, commencing on January 1st, the price of treating lead ores at the Trial smelter of the Consolidated Mining and Smelting Company will be reduced $1 a ton.

S. G. Blaylock, general manager of the Trail smelter, reported that a collection of British Columbia ores had been sent forward to form part of the Canadian exhibit at the British Empire Exhibition in England. These included samples of ore from various shipping mines as well as samples of smelter products. All these would be labelled appropriately. They had been sent through the agency of the government. The idea was to impress English financiers with the fact that British Columbia has customs smelter as well as many custom shippers of ore.

Lead Smelting Charges Reduced

The announcement of a new schedule in regard to lead charges at the Trail smelter was made by T. W. Bingay, comptroller of the Consolidated Mining and Smelting Co. The new schedule, he stated, would be effective from January 1st. There had been a number of difficulties to be met. Labor costs were higher than at the time of the last schedule. Coal prices were at present no better, and the peak prices were being paid for coke as in the days of the war. In fact, coke prices were just double pre-war prices.

Nevertheless, commencing at the first of the new year there would be a decrease of 50 cents a ton on the base rate in regard to the treatment of lead ores. There would also be a cut on zinc of from 30 cents to 25 cents a unit. The reduction would mean to Slocan ores about $1.00 a ton. Another adjustment is a reduction in the refining charge for the pooled lead of $1 a ton; that is, it is reduced from $15 to $14 a ton.

Policy of Consolidated

J. J. Warren, President of the Consolidated Mining and Smelting Co., in responding, asserted that it was always a pleasure to him to meet the mining people of the Kootenay. He believed that the relations between his company and the mining interests were steadily improving. In fact, he began to believe that ultimately, when he was dead, they would agree that he had not been so bad a fellow after all.

The aim of the Consolidated, backed by the C. P. R., during the past nine years, said Mr. Warren, had been to place mining on a sound basis rather than merely to make money. Consequently the establishment had been built from the foundation up rather than from the roof down. Reductions in the charges on shipments had been made as fast as had been possible. It must be remembered in that connection that only 40 per cent. of the Company's products were sold in Canada, and it was only natural that there should be some difficulties in marketing the balance in the world markets. To get the best results there must be mutual confidence. The Consolidated, he said, would not hurt the miner; in fact, it was as much interested in his success as he was himself. "If you produce he ores," said Mr. Warren, "we shall give you the best prices we can and sell the metals for the best prices we can obtain, to our mutual advantage."

The following are the officers for the coming year: - President, R. Randolph Bruce, Invermere; Vice-President, J. P. MacFadden, New Denver; Secretary-Treasurer, W. H. Burgess, Kaslo; Executive--W. A. Cameron, New Denver; Mayor James Anderson, Kaslo; E. G. Montgomery, Kimberley; W. T. McDowell, Ymir; Douglas Lay, Rossland; S. S. Fowler, Riondel; T. W. Bingay, Trail; S. G. Blaylock, Trail. H. Gigerich was reappointed Auditor.

EMMET MERCURY BOILER

A development that may interest miners, as it does the users of steam power, is the commercial-size unit of the Emmett mercury boiler, described in *Power* of Dec. 4th. Mercury is volatilized instead of water, the heavy vapour is used in turbines, and since it is still at 812 deg. F., is used in a vapour boiler to make steam. The over-all efficiency of the plant is approximately that of the old system. The mercury boiler [illegible] several months of the [illegible]. Trial runs have been satisfactory so far to hold out good hope for ultimate success.

The United States Bureau of Standards has under way a research with a view to finding a means of making silver more resistant to tarnish.

More Letters from Porcupine

I—Concerning Night Hawk Peninsular and Sundry Other Matters

The history of the Night Hawk Peninsular mine is the history of an idea, as will be perceived by those who read what follows:

The eight original Peninsular claims were staked in the year 1907. The evident reason for staking was a small outcropping of quartz, an outcropping of no particular significance. During the year 1916 Night Hawk Lake was lowered three feet, and another quartz outcrop was exposed. This was the first showing of what is now the important No. 1 vein. In the winter of 1916-17 the Bonbright Company, of New York, acquired an option on the property and started sinking on No. 1. When the shaft had been sunk to a depth of 80 feet and a small amount of drifting had been done, work ceased and the option was dropped. It will be remembered that during the whole of 1917 gold mining in Ontario was at its nadir. Incipient enterprises had little chance.

Through the initiative of the present manager, Mr. A. R. Globe, formerly assistant manager of the Hollinger, the present owners acquired the eight original (Auer) claims in 1920, along with a number of other claims on the NE-SW strike of the measures. The Ontario Government treated the Company liberally in the matter of granting certain water leases that covered subaqueous areas necessary to consolidate the Company's holdings. The present holdings of the Peninsular comprise 880 acres. Leases on 11 additional claims were dropped.

The property is situated on an irregular projection of land jutting into Night Hawk Lake from the north. It lies 11 miles from Connaught, a station on the T. & N. O. Railway's branch line between Porquis Junction and Timmins.

When Mr. Globe decided to assume the responsibility of recommending the property to his principals, the only positive evidence that he had to go on was the fact that on the 80-foot level an ore-shoot, 120 feet long and six feet wide, averaging $12 to the ton, had been drifted on. Geological deductions from the occurrence of detached outcrops constituted his indirect evidence.

The Peninsular is now a producing mine, well equipped, and possessing ore reserves more than adequate to meet the demands of its new mill. The main shaft is down 425 feet. About 4,500 feet of lateral development has been carried out. The diamond-drilling footage totals 7,840 feet. A winze is being sunk from the fourth (425-foot) level to the 550-foot level. Stoping has barely commenced. The ore-bodies, chief of which are veins Nos. 1 and 4, are exceptionally substantial. The general average gold content of the ore is between $10 and $12 per ton.

In a diagrammatic way the geology of the property may be indicated thus:- To the north lies a dyke of serpentine, striking NE-SW, and dipping to the south. Immediately to the south of the serpentine, and lying between it and the green carbonate schist, is No. 1 vein. It, also, dips to the south. Beyond the green carbonate comes No. 4 vein, which marks the contact of the green with the gray carbonate, the latter being variously denominated altered basalt, carbonated basalt, etc. In this rock are found unaltered inclusions of basalt. The last member of the petrologic group is andesite.

There are numerous smaller veins and ore-bodies, but veins Nos. 1 and 4 are the two of present major importance. At places they attain widths of more than twenty feet. No. 4, unlike No. 1, did not outcrop at the surface. It was traced on the third level by following an erratic stringer. At that level it showed a width of six feet; at the 425-foot level its width increased to more than 18 feet. Further north-easterly drifting developed a greater width.

There are points of remarkable interest about the vein system. These will be touched upon at a later date.

At successive stages of the mine's development, competent mining engineers have been called in by investors. At least seven different times the mine has survived the trial of checking and re-checking at the instance of purchasers of large blocks of stock. Not long ago it was examined by the representative of London-South African capital. As a consequence, an offer was made, a very substantial offer, the acceptance of which would have entailed the transfer of control to London. The offer was not accepted.

The 200-ton mill is now in commission. It would not have been in existence had not Mr. Globe had the temerity to recommend his associates to take a sporting chance in new territory. The fact deserves elaboration. It suffices just now to remark that, since the beginning of the Company's work, risks and expenditure have been carefully controlled. There has been ample warrant for each addition to plant. Equilibrium and stable balance are the characteristics of the enterprise.

* * *

It is a self-evident fact that the prospector in the Porcupine region feels himself the victim of unjust treatment. He believes, or is willing to believe, that mining companies and their scouts — and even the Provincial Government — are in collusion to defraud him. He is specially given to thinking that assay results have been maliciously lowered with the object of discrediting his property. To him the scout has become anathema. And for this there is at least a colour of reason.

To my mind it is unfair to all concerned for mining companies to send their field engineers on casual visits of inspection. The scout is clothed with no authority, and with no discretionary power as to expenditure. He can recommend the development, further investigation, or the purchase of mining claims; but his recommendations are assuredly more frequently ignored than acted upon. Hence both the prospector and the scout are placed in injuriously wrong positions. It is not fair to blame the scout. He acts under orders. But, as a thinking human being, he cannot believe that a cursory sampling of a property can justify him in praising or damning it. In

evitably the latter course is the easier. Hence much of the henceness of the whole miserable business.

* * *

Unquestionably the mining companies should adopt a different policy in their treatment of the prospector. Their field engineers should be empowered to make exhaustive preliminary examinations, instead of being forced to give snap judgments. The difference in expenditure would be an inconsiderable item. The *Canadian Mining Journal* will earn the gratitude alike of the defenceless prospector and of the misused scout if it does all in its power to correct this grave abuse.

* * *

There is a loose parallelism between the prospector and a rabbit that figured in a recent incident. Several French-Canadian prospectors were paying a short visit to some mining claims in a township south of Timmins. It happened that on the last night of their stay there was found to be a considerable excess of bread. At nightfall one of the men tied a loaf of bread to a stump in front of the cabin. At the right spot under the suspended loaf he set a small and powerful steel trap. In the morning the loaf had been nibbled down one edge. There was collateral evidence to show that the nibbling had ceased with extreme abruptness. A rabbit had come along, had stood up to sample the bread, had grown too confident, and had sat down on the trap. The trap had responded—for, mute but incontrovertible witness, there was the stub of the rabbit's tail in the trap, cut off as though by a skilled surgeon. Perhaps some wanderer in the bush has already shot that rabbit and woven a new, strange tale. Mr. Charles G. D. Roberts or Mr. Thompson-Seton (that reciprocating name may not be correct) might weave a story of another kind. This happens, as set forth above, to be the truth. The rabbit's narrative is not procurable. If it were, it would be poignantly confirmatory.

* * *

The suggestion made some months ago in the *Journal's* editorial columns regarding the mining *entrepreneur* is highly applicable to the real needs of the prospector. He requires interpretation and guidance. At present he must depend either upon the tender mercies of the compassionless corporation or upon the dangerous exploitation of the promoter. If companies dealt with prospectors openly and in friendly fashion, — and this is possible, no matter how utopian it sounds——giving discriminating advice and practical help, the situation would be vastly improved. Mutual confidence thus inspired would speed up work, tend to eliminate useless labour, and greatly augment the companies' chances of getting hold of good prospects.

* * *

Many, if not the majority of, prospectors feel that the Provincial Department of Mines is paying them much less attention than they deserve. The requirements for assessment work are strongly objected to, and this will be discussed in a later letter. The kernel of the nut is that the prospector looks upon the Government as either passively not friendly to him or as positively inimical. In this the prospector is, of course, wrong. But it is certain that the Government could do a great deal more for this most useful class of citizen. At present it is impossible to procure geological maps of Porcupine. The most useful publications are out of print. Recorders' offices are used primarily for the collection of revenue.

There is no valid reason why the Department should not utilize these offices as centres from which to distribute useful and timely printed matter. Pamphlets, designed expressly to help the prospector to an understanding of the geology of each district, printed both in English and in French, would be appreciated and used. Assuredly, also, prospects should engage more of the Department's attention than they now do. Technical advice is sorely needed in the townships that will sooner or later become Tisdales and Deloros.

Putting it briefly, the prospector gets precious little for his money.

J. C. MURRAY.

AN OFFER TO PROSPECTORS

Prospecting has sunk to such a low ebb in Australia that it requires an artificial stimulant. Here are details, from *Chemical Engineering and Mining Review* (Melbourne) of a recent offer to prospectors by the government of New South Wales:

The N. S. W. minister for mines, Mr. J. C. L. Fitzpatrick, announces that the reward of £1,000 offered by the government for the discovery of a new mineral field has been amended to make provision for the payment of smaller rewards, viz., £500 and £200 respectively, for the discovery of fields of less magnitude, and that the scope of the rewards has been increased by the addition of chromite, manganese, molybdenite, scheelite, wolfram, platinoid metals, bismuth, aunite, asbestos, bauxite or clays containing free alumina, magnesite and slate to the minerals specified in the previous notice, viz., gold, tin, silver, copper, lead, diamonds, precious opal, mercury and platinum.

The conditions of the latest rewards are:—

(1) (a) The sum of one thousand pounds (£1,000) if it be proved to the satisaction of the minister that within 24 months after he has been notified of such discovery not less than 250 miners have been profitably employed in mining continuously for at least three months within a radius of five miles of such discovery.

(b) The sum of £500 if it be proved to the satisfaction of the minister that within 24 months after he has been notified of such discovery not less than 125 miners have been profitably employed in mining continuously for at least three months within a radius of five miles of such discovery.

(c) The sum of £200 if it be proved to the satisfaction of the minister that within 12 months after he has been notified of such discovery not less than 50 miners have been profiably employed in mining continuously for at least three months within a radius of five miles of such discovery.

(2) That the site of the discovery be distant not less than 10 miles from the nearest mine in which similar payable mineral has been or is being obtained.

(3) That such discovery be made known to the minister for mines within three months after such discovery or such further time as appears, under the circumstances, to the minister to be reasonable.

(4) That only one reward shall be paid for any discovery within the area described in clause 1.

All previous notices of rewards for the discovery of mineral fields are cancelled by the new notice, which operates as from October 3.

It is reported that a Dutch company is to erect iron blast furnaces in Borneo in the near future.

NEW MODDERFONTEIN REPORT

The annual report for the year ending June 30th last of the New Modderfontein Gold Mining Company, one of the most important mining companies in South Africa, was presented to the share-holders by the chairman, Sir Evelyn Walkers, in Johannesburg on November 6th. Some of the information he gives affords an interesting comparison with gold mining in Ontario, particularly at the Hollinger. The report includes the following paragraphs:

"The net profit amounted to £1,678,418, and this figure, which includes the working profit of £1,653,481, has only once been exceeded in the history of the mine, namely for the year 1920-1921, when the price of gold was very much higher. But with the price of gold taken at its standard value, a striking difference is seen in the total working profit earned in the two periods; on this basis the profit amounted to £847,-625 for the year ended 30th June, 1921, whereas it was £1,540,897 for the year ended 30th June, 1923. I have purposely avoided making a comparison with the year 1921-1922, owing to the strike which dislocated operations so seriously in that year and which therefore renders impossible any true comparison between the two years' results.

"The main disbursements for operating profits are two dividends of 50 per cent. each, [the share capital is £1,400,000] accounting for £1,400,000 and the payment of Government and Provincial taxes for the year, totaling no less than £241,958.

Increased Efficiency of Miners

"With regard to the past year's operations, I must draw your attention to the following facts: (1) a record tonnage of 1,340,000 tons was crushed, being 257,000 tons greater than the tonnage crushed in 1920-21, the next best year; (2) working costs averaged 16s. 8d. per ton milled, showing a satisfactory reduction as compared with the costs of the two previous years, and being bettered only on two occasions, namely, in the years ended June 30, 1910, and 1915; (3) the ore reserve of 9,060,800 tons at 8.8 dwts. stands both in tonnage and value at a higher figure than at any time in the past ; (4) the ore developed during the year, amounting to 1,653,700 tons valued at 11.5 dwts., is greater both in tonnage and value than that for any preceding year; and (5) the development footage accomplished, of 23,581 feet, has only been exceeded on one occasion in the past, namely, in 1917, when the total footage of development work was 27,117 feet. [A pennyweight is one-twentieth of a troy ounce, and therefore one dwt. of gold is worth approximately one dollar.]

"The improved results shown above are undoubtedly due to the reorganization of underground working conditions effected after the strike of 1922 and to the improved efficiency of both white and native workers. It is an admitted fact, which we are glad to acknowledge, that since the upheaval the company's white employees have paid more attention to their duties and their service to the company which affords them employment. The improved spirit which has prevailed and the example so afforded have necessarily permeated throughout all sections of the mine to the native workers, who also have willingly responded in a marked degree.

"The following few examples of the increased efficiency will serve to illustrate this point:

"Fathomage broken per machine shift, July to December, 1921, .993; July to December, 1922, 1.383; January to June, 1923, 1.442.

"Tons handled per underground native per month: July to December, 1921, 28.3; July to December, 1922, 29.4; January to June, 1923, 29.5.

"Average monthly tonnage crushed: July to December, 1921, 102,800; July to December, 1922, 110,-700; January to June, 1923, 112,700.

"Cost of producing 1 oz. of fine gold: July to December, 1921, 46s. 6d.; July to December, 1922, 36s.; January to June, 1923, 34s. 7d.

Economies from Research

"From the foregoing figures you will observe the extent to which efficiency has increased. But it would be misleading if I omitted to mention that these improved results have been brought about not only by the greater efforts on the part of employees, but also by more and better facilities provided by the mine. Experiments are constantly being carried out to secure better quality drilling steel, better supplies of compressed air and better results from explosives. It is obvious that success in these directions can only be attained by the expenditure of considerable sums of money and by much time and thought given by the technical officials employed by and associated with the mine. That a considerable measure of success has already been achieved is admitted by all concerned; and there is every reason to suppose that further advances in mining practice will be made, as time goes along, to the benefit of the whole gold mining industry.

Ore Reserves

"Turning now in more detail to the past year's mining operations, you will observe that the ore milled amounted to 1,340,000 tons, and the yield per ton was 9.4 dwt. The payable ore developed amounted to 1,-653,700 tons, valued at 11.5 dwt., with the result that an improvement has been shown not only in the tonnage, but in the value of the ore reserve. The ore reserve, as re-estimated at June 30th last, amounted to 9,060,800 tons, valued at 8.8 dwt. over an average width of 66 inches, and it is not necessary for me to elaborate the point that the mine is in an exceedingly strong position.

Corduroy Concentration

"In metallurgical practice the results achieved during the period under review were entirely satisfactory. The introduction of corduroy blankets in replacement of the amalagamation plates can be definitely stated to be a successful innovation, as is shown by the fact that, whereas the cost of plate amalagamation per ton milled was 3.2d. in 1921 and 3.4d. in 1922 (excluding the three months' strike period) the cost of corduroy concentration during the first nine months of 1923 was 1.9d. only. The latter figure includes non-recurrent expenditure on account of the extra equipment required and the necessary alterations to the reduction plant, so that we may expect it to be improved on in future. Every precaution is taken to safeguard the health of employees in the reduction works and to minimise the opportunities of theft of gold, our endeavour in these two directions being greatly assisted by the change-over to corduroy concentration.

South African and Ontario Taxes

"You will observe from the directors' report that your company paid Government and Provincial taxes during the past year amounting to no less than £241,-958, quite apart from the annual sum of £17,310 pay-

able to the Government in respect of undermining rights lease. In other words, Government and Provincial taxes alone absorbed 14.4 per cent. of the company's net profits. One cannot but envy the shareholders of, say, the Hollinger Consolidated Gold Mines of Canada, whose property is in some respects comparable to your own, but is fortunately situated in Ontario, where taxation is levied at a more reasonable rate."

STUDIES OF FLOTATION

The issuance of Technical Paper 262. "Certain interfacial tension equilibria important in flotation," by Will H. Coghill and Carl C. Anderson, is announced by the United States Department of the Interior, through the Bureau of Mines. The report contains the results of investigative work performed under a cooperative agreement between the Bureau of Mines and the University of Washington.

The successful use of flotation for separating ores and the uncertainties surrounding the observed facts have resulted in an extensive literature. As a consequence many physical and chemical principles that otherwise would have been regarded as foreign to the metallurgical field have been called to attention and offered in explanation of the phenomena observed.

Present Knowledge Empirical

Some idea of the tremendous importance of flotation as an industrial process is obtained from the fact that in a recent year it was utilized in treating some 70 million tons of ore. However, although this process profoundly influences modern practice in ore concentration, knowledge regarding it is largely empirical. For this reason writers have studied some of the principles often mentioned in the literature.

In part I of this paper, the authors discuss the equilibrium of the interfacial tension forces of two liquids and a gas. The Neumann equilibrium triangle was employed jointly with cathetometer observations of a lens of one liquid resting on another. The angles derived by the use of the Neumann triangle and those derived by principles of mechanics have been compared.

The configuration of the surfaces and the interface of a lens of one liquid resting on another has been shown in detail by drawings.

The following combinations were studied — paraffin oil on water, carbon tetrachloride on water, aqueous sodium oleate and benzene, aqueous acetic acid, and paraffin oil.

The analogy of the flotation of a heavy liquid and of a solid, each floating by "film suspension," has been discussed.

Studies of Surface Tension

In Part II, the authors consider the surface-tension phenomena of a solid, a liquid, and a gas in contact; the angle of contact and the edge effect.

The Neumann equilibrium triangle can not be used in a consideration of the interfacial forces of a system containing a solid, a liquid, and a gas, but by co-ordinating the surface energy of a solid with the surface tension of a liquid, an equation containing the angle of contact of a liquid with a solid may be used. The angle of contact bears the same relation to the interfacial energies of the sytem, solid-liquid-gas, as the Neumann equilibrium triangle does to the interfacial tensions (or energies) of the system, liquid-liquid-gas.

The phenomenon of the overfilled tumbler is described. The difference in size of floatable bodies of cylindrical shape and of prismatic shape is brought out. The edge effect was studied by making cathetometer measurements of the heights attained, before overflowing, by pure and modified liquids on beveled glass plates having various solid angles.

From a consideration of the curve representing the profile of the surface of a liquid meeting a solid and of the angle of contact the theoretical heights that liquids will attain on horizontal plates before overflowing were determined. An explanation of why a liquid is reluctant to cross a convex edge is given; the liquid's deportment depends on the dip of the face it meets after crossing the edge.

Edge Effect

The principle of edge effect explains why mineral floats away by film suspension in the gold sluices, on the concentrating table, and on the film-suspension flotation machine.

A liquid may make a small angle of contact against a plane face of a solid in massive form, and in turn make a large angle against the same material powdered and cemented on a plate.

The contact angle is closely related to the spreading power of a liquid on a solid; when it is zero, the liquid is said to spread on or wet the solid. Amalgamating, tinning, galvanizing, and leading are examples of spreading. As spreading takes place, the inequality of the interfacial tensions acting in any one of these is indicated. Minute traces of contaminants often suffice to prevent the spreading of a liquid on a solid. A consideration of the subject of spreading is essential in obtaining efficient coal dust sprays, detergents, animal dips, horticultural sprays, etc.

Technical Paper 26 may be obtained from the Department of the Interior, Bureau of Mines, Washington, D. C.

CANADIAN HOLDINGS OF ASSOCIATED GOLD MINES OF WESTERN AUSTRALIA

The annual meeting of Associated Goldfields of Western Australia was held in London on Dec. 14th. The directors' report shows that the company owns 31,800 shares of the Huronian Belt Company's 200,000 shares of £1 each; 474,636 shares of the Keeley's 2,000,000 shares of $1 each; and 327,671 shares of the Vipond 2,000,000 shares of $1 each. Apart from being a large holder of Keeley, Vipond, and Associated shares, the Huronian Belt Company owns, and is interested in, a number of claims in close proximity to the Keeley mine, and is actively engaged in opening up the Maidens property in the South Lorrain district, situated on a geological formation similar to that of the Keeley mine. The Company also owns a large number of claims, options, and other interests in several mining fields of Northern Ontario, on which prospecting work was started during the summer and will be actively resumed in the spring. The report also mentions the fact that the Keeley produced 1,743,138 ounces of silver from July, 1922 to the end of October, 1923, in addition to a regular output of cobalt ore. The reserve of ore of a grade of not less than $10. per ton at the Vipond is stated to be such as to afford at least a two years' supply to the 150 ton mill, without including reserves of ore of a lower grade.

Canada's Mineral Industry

Some Encouraging Facts Cited, in Rebuttal of Mr. C. M. Campbell's Conclusions

Mr. C. M. Campbell's papers on "Publicity and Mining," presented at the Trail meeting of the Institute in October and published in the December *Bulletin*, has brought an avalanche of criticism in the January *Bulletin*. As this brings out important points that have not, in the main, been incorporated in this discussion previously, salient paragraphs are reproduced below. The first part of the discussion is by Dr. C. V. Corless, as follows (in abstract):

Dr. Corless Paints a Picture

It is a depressing picture we have presented to us in the December *Bulletin*. To quote a paragraph (page 647):

"Let us now pass on to another phase of the situation. As you go South from the 49th parallel, along the prairies, you pass through wheatfields, then cornfields, and then through fields of cotton to a sea where there is perpetual summer. Travelling north, however, you pass through wheatfields to an area where the trees get smaller and smaller and finally disappear. You then pass through the Barren Grounds where only grass will grow in the summer. Finally you reach what Captain Markham called the "paleocrystic sea," along the shores of which are scattered the bones of explorers from Franklin to Crawford."

How much publicity of this kind, particularly if its source is the C. I. M. M. and and its medium the *Bulletin*, will be necessary to stop all immigration and swell the tide of emigration until Canada's population dwindles to insignificant numbers?

Isolated facts are but the pigments of a picture. We may select and combine them in any way we please, creating at our will either a true or a false impression. Though the facts selected and combined may be true, the resulting impression caused by the picture may be wholly false. Reason and judgment are our only guide, if we are seeking to impart the truth rather than to create a merely artistic effect.

To illustrate: It is easily possible to reverse the effect of the author's above description by similarly selecting and combining facts along other north and south lines crossing our international boundary. We might select a second line of travel, passing through the famous fertile lands of the Peace River district and the western section of the Canadian prairie, where cattle may remain in the open all winter; passing across snow-clad peaks of the Rockies; and ending in the desert of Arizona or New Mexico. Probably more bones of explorers would be found near the southern end of this line than are depicted as scattered along the northern end of that described in the paragraph quoted. Or, we might, with equal reason, select a third north and south route, slightly west of the 79th west meridian and paint a magnificent picture of the Canadian end of it; as crossing two of our great treasure-laden inland seas, between which lies one of the world's finest and most productive fruit belts; passing great and prosperous cities and highly developed farms, all supplied with power and light from one of Nature's greatest scenic wonders near at hand; on into a territory dotted with myriads of beautiful lakes, which is fast becoming the play and sporting ground for our southern neighbours, when they are driven from their cities by the insufferable summer heat; past new but thriving towns springing up because of untold hidden wealth in nickel, copper, silver and gold; past other flourishing communities rising from some of the world's greatest forest industries in lumber and paper; across a second broad belt of highly fertile land, as extensive as that already crossed, opened up by railways and lying ready for the settler; and on to the shores of the world's third largest mediterranean, teeming with fish and game and surrounded by mineral lands a sea destined to bear the argosies laden with the farming wealth of Canada's productive western plains.

Harmful Effects of Sombre Picture

If the author's purpose was not to depreciate his country, and particularly his native province, why did he deliberately seek publicity for such a dismal picture as this? No Canadian, well-informed about his country, will accept it as truly representative. But because there are hundreds who are not well-informed, for every one who is, the impression created by such an over-drawn description may do vast harm.

It is the utterly false impression of Canada, created by such descriptive paragraphs as this, that has been one of our country's greatest handicaps in its development. How any Canadian, with real knowledge of his country and the kind of red blood in his veins resulting from our wholesome pioneering life and our invigorating climate, can deliberately sponsor such publicity as this, is beyond my understanding.

* * *

The author next attributes to me the statement, "that this two-thirds (of Manitoba) will produce 'inconceivable wealth in minerals,' that here 'the only permanent industry is or will be mining.' "My statement in the former case was made of the entire pre-Cambrian, of which the part in Manitoba is roughly only about one-twelfth. In the latter case my statement was made regarding the great non-agricultural part of Canada as a whole. Besides these misrepresentations, the author has omitted two important words which greatly change the meaning, though he encloses the words in quotation marks, as if the quotation were exact. Now the only worthy purpose of criticism is to get at the truth. This very unusual method of criticism seems to indicate that the author's conception of its purpose is to score a point.

* * *

The author speaks very grudgingly of the great mining achievements already made in what he chooses to refer to as "that prolific section in northern United States and Canada which has been so frequently referred to," mentioning in turn the iron, copper, nickel, silver and gold, and dismissing each with a passing grouch, of too childish a nature to deserve serious criticism. His remarks regarding recent silver and gold discoveries indicate that he is badly out of touch with developments in these areas within the past 3 or 4 years. These five great mining areas are well able to speak for themselves and each of them has so long a future before it that there need be no worry for many years to come regarding their not being duplicated. Discoveries are in fact still being made in all those in Ontario. In the case of some of them, production is indeed but little more than well started.

Need of Intensive Prospecting

The author's final conclusion regarding the pre-Cambrian (page 666), that the great need is intensive pros-

pecting, consisting in detailed geological work, trenching, diamond drilling, etc., and his statement that this demands large capital outlay, constitute, in my judgment, the most valuable part of his paper. This view is in exact accord with my own, as expressed in the paper which he so persistently attacks and as repeatedly emphasized in later discussions. A discussion of the respective parts in this work proper to the government, the prospector, and the mining syndicate or company, would be of very great interest but lies outside the purpose of the present criticism.

But, though I am glad to find that the author and myself are in agreement on this point, I frankly admit that our views appears to be poles apart on others. And one at least of our points of difference appears to consist in this: I believe wholeheartedly in the vast extent of our mineral wealth; consider, therefore, the admittedly large expense necessary for intensive search for ore, many times worth while; and, consequently, try to do what little I can to assist and to encourage this class of work; whereas, it appears to be clear from this paper and from the author's previous criticisms, that he does not believe that Canada's mineral resources are of any great extent; that this disbelief causes serious misgivings as to the justifiability of entering into such expenditure of capital in the search for mineral, which may not, and probably does not exist, or which, if it does exist, is concealed by such insuperable difficulties as to make search for it almost futile; and that he is, therefore, apparently trying to discourage the search for valuable minerals by magnifying their supposed scarcity and the difficulties to be overcome in the search for them.

* * *

The mining industry will have its ups and downs. But such close intelligent co-operation as we now have in Ontario, among geologists, prospectors, mining engineers and capitalists, if only we can keep the crooked promoter, wildcatter, and broker from diverting capital from the actual work on and in the ground, will rapidly bring mining to the very fore-front of our basic industries.

The United States has three times our possible farming area, yet mining has overtaken agriculture in that country. With our vast areas, in which this kind of detailed prospecting is possible and in which we now have almost irresistible reason for believing vast mineral wealth to lie hidden, Canada's mining industry will probably overtake her present greatest basic industry, agriculture, long before her population approaches the existing population of the United States, particularly, if Canadians in the near future awake to the national necessity of supplying themselves with those basic industrial requirements—coal, iron and steel.

* * *

Long-Lived Mining Camps

I note, that the mineral resources in which our country is known to lead or to stand very high are either dismissed by the author with a disparaging remark, or pass unnoticed altogether. Of the nickel he says (page 665): "It is 40 years since the Sudbury deposits were discovered and these finds have not been duplicated." I should think not. The ore in the Sudbury nickel area is not yet all discovered. Again, our asbestos deposits, in which Canada leads the world, are not even mentioned. Of our nickel, silver, and gold deposits, at Sudbury, Cobalt, and Porcupine, he says (page 649): "even there there is no certainty of indefinite life." The author must surely mean perpetual life:, the productive life of these districts is surely "indefinite" enough when all three factors that could make their life definite, viz., number and extent of orebodies, as well as rate of mining, are unknown. No mine has a perpetual life. The life of very few mines is definite.

* * *

Now, as I have recently stated in the *Canadian Mining Journal,* I am whole-heartedly in sympathy with the author in his zeal for economy and sanity in the development of Canada's natural resources. But that he should make the expression of his views on this matter the occasion for so violent an eruption against his own industry as to necessitate the bolstering up of weak argument by the use of mis-statements, mis-representation, and even mis-quotation —carelessly, —seems to indicate so illogical a relationship of ideas as to suggest a brain-storm. Just why the mining industry should be selected and pilloried, as if accountable, in some obscure way, for the greater part if not all of Canada's economic and other mistakes and difficulties — from destruction of scenic beauty, rash expenditure of money in cities, and over-fishing of one of our many rivers, to over-expansion of our railways, and even to severity of climate in some parts of our half-continent — is a question that may well puzzle any reader, who desires to delve beneath the charm of artistic literary style, and who wishes to grasp and weigh critically the realities dealt with as well as to try to estimate the probable harvest to be reaped from this kind of publicity.

* * *

We should also consider with great care, the effect of such papers on the minds of those to whom the industry must look for capital to carry on the work of detailed prospecting. If it comes to be widely believed that any considerable number of our members hold the views expressed in this paper and in some other of the recent statements of its author, the mining industry in Canada, will have been done untold injury.

Professor Mickle's Argument

The following paragraphs from Prof. G. R. Mickle's remarks illustrate well the logic of his argument:

I have read Mr. C. M. Campbell's paper with the above-mentioned title and agree with many of his remarks in so far as he deplores the waste and destruction of our resources and ridicules extravagant ventures based on a gambler's hopes. By all means let us be accurate and call the surveyor who makes an absolute mistake to account, as Mr. Campbell says we should. The writer who uses a wrong mode of reasoning with regard to estimates of the future should, I think, also be called to account. Mr. Campbell in this paper follows what I consider is the same fatal fallacy that he has in previous writings, one of which was quoted and commented on in the December 1922 *Bulletin.* Mr. Campbell still adheres to the same idea of the measured ore body as the only guide to the amount of production in the future. Dr. Corless has alluded to this phase of the matter in the following way: "A few years ago we heard more discussion about estimating proven ore reserves than about applying knowledge and reason to finding ore. No doubt these discussions did some good but they also had a somewhat deadening effect. Now the mining engineer who does not look beyond the ore he can measure, who is not intent on using ascertained facts as a stepping stone to probabilities, will not get very far." (Trans. Can. Inst. M. and M., vol. 25, p. 23.) I should think it had a deadening effect! Let us see why its use and application is only limited and why [illegible] too low and is therefore useless. As an example we will take the [illegible] early productive life of this organization. The following figures are taken from the reports for the years in question.

Nipissing Mines Co.

1909

Production for year 1909	4,728,131 oz.
Reserves (developed and partly developed ore)	6,552,880 oz.
Total production to end of 1909	12,747,468 oz.

1910

Production for 1910	5,548,660 oz.
Reserves (developed and partly developed ore). The large tonnage of mill rock on the dumps and in the mines is not covered by the estimates.	6,552,880 oz.

1911

Production for 1911	5,197,042 oz.
Reserves (developed and partly developed ore)	6,126,838 oz.
Mill rock on dumps	4,151,995 oz.

1912

Production for 1912	4,688,261 oz.
Reserves (developed and partly developed ore)	5,491,343 oz.
Mill rock on dumps	4,151,995 oz.
Production to end of 1922	65,700,579 oz.

And still at a substantial rate.

Anyone following Mr. Campbell's mode of reasoning if he had been asked at the end of 1909 to give a forecast of how much more silver the mines owned by this company would produce would have to take the reserves (which include only partly developed ore) and say 7 million ounces approximately, whereas we see after 1909 it is about 53 million ounces to the end of 1922 only, and production still going on at a substantial rate. Seven million would have been an obviously ridiculous estimate. A similar result would be seen if any mine which could reasonably be considered productive were taken in its early productive life. And it is precisely this kind of mine which is the hope of the mining industry as the young apple tree just coming into bearing is the hope of the orchard. The blocked out and measured ore is a true measure of the complete ultimate production only in cases where the production either never will amount to anything very important or approaching the end of the life of a good productive mine. It is clear moreover that the productive mine, by this I mean the mine that works for a reasonable term of years, will almost always be the main source of production of any given metal or product, and that the percentage derived from any kind of mine except the productive ore during its prosperous period is small, probably not over 10 or 20 per cent of the whole. The measured ore body is thus a true indicator only for a small percentage of the output for the future.

Mr. Haggen's Data

Mr. E. A. Haggen, of Vancouver, editor of the *Engineering and Mining Record,* contributes the following pertinent remarks to the discussion:—

The following statement was recently published by me:—"Dr. C. V. Corless, General Manager of the Mond Nickel Company Ltd., Coniston, Ontario, rendered a national service when he pointed out that while it was customary to regard Canada as an agricultural country, the ratio of agricultural lands to the whole is only 15 per cent, whereas the mineral area of the country amounts to 85 per cent."

This forms the text of a fresh outburst on the part of Mr. C. M. Campbell in a paper read at the Trail Meeting. The paper as published in the December *Bulletin,* has, however, undergone elimination of the several personal references made to Dr. Corless and myself, evidently as the result of the brief criticism to which the paper was subjected.

In my opinion the P. G. E. railway is the most important colonization and transportation project yet promulgated in B. C. and I know the country. It was originally planned to provide transportation to the most important agricultural section of the province, namely Peace river, with its 60,000,000 acres of wheat lands. The route adopted was that formerly proposed by the late James J. Hill, one of the foremost railroad men on the continent. Unfortunately the scheme got into politics, and millions of dollars have been squandered on it for which no value has been received. It is still without a terminal at either end and yet, since it has been placed under expert railway management, it is now pretty well covering operating expenses and increasing its traffic. Contrary to Mr. Campbell's statement, the Britannia mine is on the route of construction of the Howe Sound section, and it also provides with transportation the well-known mining field of Cariboo, where dredging operations are being inaugurated by an English company, after thoroughly testing its ground.

But it is with Mr. Campbell's observations on the mineral industry I wish to deal. His claim that the industry has not delivered the goods is confounded by the facts that in 37 years its wealth production has grown from $10,000,000 to about $200,000,000 a year; its per capita value from $2.23 to $25; its total to date amounting to $3,200,000, or $465 per capita.

His diagram, Fig. 1, is not applicable to a discussion on basic industries founded on natural resources, as manufactures are largely dependent on imported raw materials; and a considerable proportion is derived from mineral production with which that industry might properly be credited. Judging from his remarks accompanying Fig. 2, he appears to be under the delusion that he is the only honest mining engineer we have. The value of graphics, properly presented, has been endorsed by some fifteen leading engineering organizations.

He admits "'records of dividends make good copy." They do more. They are the best index of investment value. What are these records? The mines of Canada have paid in dividends about 10 per cent of the value of the production. They have contributed a similar proportion to depreciation, depletion, equipment, and the development of reserves, consonant with the nature of the industry as a wasting asset and the "risk of the business." Mr. Campbell cannot point to any other basic industry with that record. The industry is not responsible for the capital losses made in wildcat flotations and watered stock.

With reference to the complaint that British Columbia has not produced a Chile Copper and a Utah Copper. It took 50 years from the first mining of copper in the United States to discover Utah Copper. It took Chile 500 years from the inception of its mining industry to discover Chile Copper. Copper mining in British Columbia is not yet 30 years of age. Give the province the same time as the United States and Mr. Campbell may find himself among the false prophets.

The mineral industry of British Columbia has nothing to be ashamed of. In that period it has developed the largest silver-lead-zinc mine in the world; the three largest copper mines, the two largest concentrating plants for copper ores, the two largest copper smelters, in the Empire; and one of the most important metallurgical enterprises in the world. It is achievement that counts rather than the visions of a timorous dreamer. Coast Range granite which used to be regarded as Mr. Campbell regards the Laurentian, has produced within its boundaries, the Britannia, Marble Bay, Surf Inlet, Hidden Creek, Ecstall, Outsider, and Premier mines. As to the mining engineers seeing nothing but mining, I have met more far-seeing, broad-minded, high standard men among our mining engineers than in other classes of the community, and I could name men in that profession who could manage the public business of the Dominion and its Provinces much more efficiently than is now being done.

Some Recent Developments in Steel Wire Ropes*

By T. ALBERT TAYLOR†

The evolution of the wire rope, from a crude construction of iron or mild steel wire to the complex high-tensile steel "super-ropes" — that to-day are such indispensable adjuncts to up-to-date mining equipment —is one that has developed during comparatively recent years. New types of ropes have been placed on the market; some of these have failed in actual practice to justify the claims of their inventors, while others have been perfected by improved manufacturing methods and machinery, so that they have now become recognised as distinct improvements. At the same time new kinds of steel have been introduced in order to supply the demands of wire rope manufacturers for stronger and still stronger material until the wire rope has reached a degree of strength and reliability that could never have been deemed possible by the early wire rope maker.

Where in the old days one type of rope was made to answer every requirement—the only difference being the number and size of the wires employed —to-day wire rope making has become an exact science, and a selection from dozens of different constructions is possible, while the choice of material has also been greatly extended, so that, given a knowledge of the work to be done and the local conditions, there is no reason why the modern ropemaker who has the necessary experience and equipment should not be able to supply ropes that will give every satisfaction.

When it is considered that the wire selected may be any one of a hundred different grades, qualities, and shapes, and the size will be one of a range of nearly 150 different gauge sizes, it can be understood that the introduction of the new types of rope has rendered a large tested stock very necessary where quick deliveries are desired.

In order to get the best results, the wire rope maker has therefore not only to decide on the type, size and pattern of the component wires, and the quality of material to be used, but he must also know the wire drawer who can be best depended upon to make that particular wire so that it will successfully pass the various tests. In this selection practically the only guides are "trial and error."

It is generally recognised that where heat treatment is required during the process of manufacture the final result is often variable, and for this reason it has been found that while some wire drawers can be depended upon for one class of wire, other makers can supply other qualities and types that will be more satisfactory.

Winding Ropes.

Following the advance of modern practice, the work done by the winding rope has increased enormously of late years, and to-day this portion of the winding gear is a pulsating, palpitating and vibrating unit, as the momentary intervals of rest are insufficient to allow the vibration in certain portions of the rope to die out. Add to this the effect of dynamic stresses such as are imposed when the load is applied and is being accelerated or decelerated, the bending of the rope on the pulleys and drum, and other external influences, and one can have some idea of the constant change which must be taking place both in the rope as a whole and in the structure of the material composing it.

The choice of a suitable type for rapid and deep winding under the conditions that apply to-day is one that demands the closest attention. The ordinary round strand rope that answered the purpose for our grand fathers was practically superseded by the Lang's lay round strand rope that for another generation was recognised generally as the most suitable. The introduction of the locked coil and flattened strand ropes nearly 40 years ago marked an advance that was not recognised at the time. The conditions then were not so strenuous that these types of ropes were so necessary as they have since become.

Locked Coil Rope

When the locked coil rope was patented in 1884 the advantage claimed for this was the use of external wires of such a shape that in the event of a wire breaking it would not detach itself from the rope, but be locked in position. In practice, this rope has been so developed that many more important advantages have been obtained, the principal being that the rope is absolutely non-spinning, so that for deep winding, where wear on guides or shoes is often considerable, also where there is a possibility of collision in the shaft owing to small cage clearance this type is indispensable. For sinking, without guides, no other rope is so satisfactory.

Locked coil ropes are 44 per cent. stronger, size for size, than round strand ropes whilst strength for strength they are 16½ per cent. less in size and 2 per cent. lighter, thus enabling smaller ropes to be used. The maximum elongation of a properly constructed locked coil rope is only 0.3 per cent. (about one-twentieth of the elongation that takes place in round strand rope) and adjustments necessitated by this cause are practically negligible. Also, when a new installation of winding gear is being considered, this type of rope demands consideration, as where a locked coil winding rope is adopted, and thus a smaller rope can be used, there is a corresponding saving in the drum width and size of the winding plant; in fact, it has been estimated that in this [illegible] saving of 10 per cent. may be effected.

[illegible] original method of constructing locked coil ropes, namely, with alternating direction of lay of each concentric [illegible] a consequent twisting of the wires in use, and this method has now been considerably improved upon by the writer's firm, who have eliminated this most dangerous feature. The locked coil rope in its improved form provides a satisfactory solution to [illegible] problems [illegible] for raising maximum loads from great depths it is unrivalled. A large number of these ropes [illegible] are giving satisfactory [illegible]. Among those may be mentioned particularly [illegible] of the circumference,

* From a paper read before the Birmingham Canadian Mining Society, March [illegible], and published in the Mining and Engineering Journal.

† Director of John and Edgar Wright, Ltd., Birmingham.

having a breaking strain of over 300 tons, and which carries a total dead weight of 35½ tons. A locked coil rope of 6¼ in. circumference has recently been taken off after raising nearly a million tons of coal from a deep pit; while another rope, of 6¾ in. circumference and over 1,000 yd. in length, is giving satisfactory service under most strenuous conditions.

Naturally, to obtain such results great care has to be exercised in the manufacture of the ropes, and considerable progress has been made in this direction. The question of internal lubrication has received particular attention, ropes being now packed with a special compound of suitable viscosity as they are built up, the final concentric layer forming a complete lock, so that the inside portion of the rope may be regarded as working in a bath of grease. This lubricant cannot escape, and it not only prevents the entry of moisture, dirt and corrosive fumes, but reduces the internal friction of the inside wires, whilst, owing to the special method of laying up the rope, the insidious danger of cross-cutting, before referred to, is avoided.

Triangular Flattened Strand

Whilst the locked coil winding rope is undoubtedly the most suitable for new installations, it often happens that when an existing colliery is being re-designed to produce a greater output, or it has become necessary to wind from a greater depth or carry a heavier load a stronger and better rope is required. Under these conditions the existing round strand rope may be replaced to advantage by a compound triangular flattened strand rope, and this type is also sometimes adopted for new plants. It is also recommended for use in South Africa, where winding conditions are much more involved than in Great Britain, owing to the use of compound shafts and indirect leads from drum to headgear sheaves: as in many cases the rope winds on its own parts, a rope of the triangular flattened strand construction will successfully withstand the crushing effects of the various layers.

The compound triangular flattened strand rope is composed of strands which, being built up in a triangular shape, fit in "keystone" fashion into the rope. By this means a greater cross-sectional area is obtained, resulting in the rope being 12½ per cent. stronger than a round strand rope of equal size. The surface of the strands exposed for wear is therefore much greater, so that frictional wear is distributed over a number of wires instead of on the crown wires only, as in round strand ropes, the result being a longer life service. In addition, this type of rope, owing to its special construction, possesses valuable non-rotating and non-stretching qualities. These ropes have been supplied in all sizes up to 6¾ in. in circumference; they almost invariably give the full period of use permitted by the law, and, when removed, appear to be little the worse for wear.

In addition to this type of flattened strand rope, there is a concentric non-rotating flattened strand rope, which consists of concentric layers of flat strands so laid up as to effectually prevent any rotation of the rope in use, and by this method increased solidity and strength are obtained. This construction has been found invaluable for conditions where locked coil ropes cannot be used, and for winding on the Koepe principle they have been found to be the most satisfactory type.

Guide and Balance Ropes

Improvements have also been brought about in pit shaft ropes and for this purpose the use of locked coil guides, in either half or full locked construction, is recommended. These guide ropes are much more economical in use than the old types, as not only is a greater and better surface presented for wear, but they have the enormous advantage that in the event of a rod breaking, it is held in place by those adjacent to it, and thus prevented from catching the cage, with possibly disastrous results. In addition to this, modern practice has demanded a type of guide rope for use at great depths, which will carry the load necessary to keep it taut, in addition to its own weight. This necessitates the use of high-tensile steel, instead of the mild steel or iron previously employed, and it is obvious that this could only be safely employed on the locked coil construction.

The same remarks apply to rubbing ropes, which are placed in the centre of the shaft with the object of preventing a collision between the cages as they pass.

Flexible locked coil ropes are now preferred to all others for shaft scaffold guide ropes, for which purpose they are particularly suitable.

For balance ropes, for attachment to underside of cages, flexible mild steel round strand ropes of ordinary lay, or flat ropes can be used, but non-rotating flattened strand ropes are recommended, as they will give better service under any conditions.

Haulage Ropes

The problem of how to overcome the excessive frictional wear on haulage ropes, whilst at the same time obtaining a stronger rope, has exercised the minds of rope manufacturers very considerably, especially where the rope winds upon itself on to a drum. After experimenting with many types of rope, a triangular flattened strand rope of a modified type has been developed for "drift" haulage, and this has proved to be vastly in advance of any type of round strand rope yet devised. The increased wearing surface obtained by the flattened strand construction, combined with resistance to crushing on the drum, together with a higher factor of safety due to its increased strength, makes this type extremely successful, so much so, that many large concerns have now adopted compound triangular flattened strand haulage ropes on all their "slants."

Important economies have also been obtained by the use of flattened strand haulage rope for endless or main-and-tail mechanical haulage, as for the former purpose the "keystone" formation resists the crushing effect of the grips, rendering a wire main unnecessary, and therefore the rope can be made lighter and more flexible.

Aerial Ropes

Many mining concerns now employ an aerial ropeway for the handling of minerals, etc., or for the disposal of waste products; and these are usually of the bi-cable type—a fixed rope upon which the carriers run, drawn by a smaller haulage rope. In the early types of carrying cables used, viz., spiral and early locked coil ropes, the pressure of the carrier wheels upon the main cable caused considerable internal cross-cutting, while the vibrations caused by haulage gave rise to crystallisation and fatigue in the material near to the support.

These drawbacks have now been successfully overcome, and the present type of locked coil rope supplied for aerial ropeways has large external wires to take the

wear, is free from cross-cutting internally, and the material, being of special toughness and ductility, is not subject to crystallisation, whilst the internal wires are efficiently lubricated. Full-locked ropes are recommended on account of their greater smoothness, which reduces tractive effort, and because the ropes may be worn down much further than the half-lock type; the latter is often preferred, however, on account of its lower initial cost.

Conclusion

In the course of designing and the manufacture of these super-ropes an enormous amount of valuable experience has been obtained, together with data of far-reaching importance that has repaid to some extent the enormous cost of exploiting and testing the different types, a labour entailing the investigation of working conditions on the spot, much research work, the use of special materials hitherto unused by wire rope makers, and the building of special machinery to improve constructional methods. That this expense was justified is proved by the fact that ropes of these special constructions are now being adopted generally by discriminating users of wire ropes, and that the old types of ropes with their various imperfections are being superseded for mining operations except for some important purposes.

THE EVERLASTING METAL

The *Granby News,* of Anyox, B. C., addresses the following to its readers, the employees of the Company:

A short time ago the management of the Granby Company distributed locally a number of copies of a splendidly illustrated brochure entitled "The Story of Yesterday and To-Day." It was published by the Copper and Brass Research Association, of which the Granby Company is a member, and had to do with the history of the metal which is being produced in Anyox, illustrating a great many of the uses to which copper has been put in connection with the modern progress of mankind, as well as bringing graphically to our notice the fact that copper was a very considerable factor in the life of man at the earliest period of the world's history so far unfolded by the earnest seekers after truth in places where evidence of ancient human life are to be found. Its alloy with tin was the first metallic compound in the use of mankind; and so extensive and characteristic was its employment in pre-historic times that the epoch is known as the Bronze age, occurring between the periods of time known as the Stone and Iron ages. A piece of copper pipe unearthed at Gizeh, near the tomb of an Egyptian king, is said my Egyptologists to be at least fifty-four hundred years old; while the life-size statue of King Tut-Ankh-Amen, a discovery fresh in the minds of everybody, and guarding the entrance to his sepulchre in the valley of the gone Egyptian monarchs, is topped with the symbolical headdress made of copper and affected by the ancient Pharoahs.

The record of this metal on the scroll of the centuries is the record of human progress; and because of its resistance to all the agents of destruction following in the wake of time, it is alone worthy of the appellation applied to it—Everlasting Metal. Until the end of time, it must continue to serve mankind; and while temporary substitutes may take its place from time to time in certain quarters, because of cheapness and false testimony nothing can take its place where service continuous and lasting, is the main consideration. It is not economy to pass up an article of copper or its compounds because an article which will serve the same purpose for the time being can be had at a slightly cheaper cost. When in doubt about this, look ahead to the time when it will be necessary to renew the purchase of the substitute, not once but probably several times for the requirements of a lifetime, and you will appreciate which is the cheaper article in the long run—the one made of copper or the one offered "just as good." It is false economy to purchase cheap goods of any description. An article cannot be cheap and good at the same time. You know that there is no worthy substitute for the metal you are assisting to produce in Anyox; and if you have no immediate reasons to "Buy Something Made of Copper," people in other places may have and not know the difference between the genuine and unworthy substitute. Advertise the virtues of the metal wherever you find listeners, for people are ever eager to listen to truths when backed by undisputed facts.

COMPRESSED AIR DATA

A pamphlet entitled "Trade Standards Adopted by the Compressed Air Society" has just been published, embodying the result of extended study and research on the part of the executives and engineers associated with the members of that organization. It embraces the nomenclature and terminology relating to air compressors and their operations; a history of the development of speeds of air compressors; an explanation of capacities and pressures; instructions for the installation and care of air compressors with illustrations of devices suggested for cleaning the intake air; recommendation for the lubrication of air compressing machines and the cleaning of air receiver piping; a description of the low pressure nozzle test recommended by the Society, and a partial list of applications of compressed air.

The Compressed Air Society publishes this pamphlet with the belief that there is a need for such an authoritative work of reference and that compressed air engineers and users as well as manufacturers of air compressors will appreciate this step toward the establishment of definite trade standards in the industry.

Copies may be had from the members or by addressing the Secretary of the Society, C. H. Rohrbach, 50 Church St., New York.

RECORD MONTHLY OUTPUT FOR RAND

In October the gold output of Rand mines totalled 793,842 ounces. This constitutes a record month for the Rand, with the exception of a month in 1912, when a special clean-up brought the total to about 8,000,000 ounces. October's fine showing is attributed to an augumented supply of native labour, as well as a market all-round increase in efficiency.

THE MINING DISTRICTS

By THE JOURNAL'S CORRESPONDENTS

BRITISH COLUMBIA

Tidewater Mine Closed. — The Tidewater Copper Co., operating on Sidney Inlet, Vancouver Island, has ceased work. Forty-five workmen reached Victoria early in December with cheques aggregating $8,000 in face value, payment of which was refused by the banks. Liens have been obtained against the property on behalf of the men under the Mechanics' Lien Act. The plight of the men was made the subject of debate in the British Columbia Legislature, now in session, when the Attorney General stated that the last shipment of concentrate from the Tidewater company, valued at $41,000, had been held up and that the government had advanced $3,000 to meet the immediate needs of the unpaid workmen.

Stewart.—More high-grade ore is reported to have been struck in the Dunwell Mine, Portland Canal. It was uncovered in the No. 2 Tunnel and is said to be similar to some of that taken from surface cuts, samples of which ran $90 in gold and 100 oz. in silver per ton.

The Canadian and American mining towns of Stewart and Hyder, Portland Canal, have been connected by road, the Public Works Department of B. C. announces. The old thoroughfare was partly over water; the new ore has been cut through rock for about one and a quarter miles.

The Porter-Idaho Syndicate, which has been organized with an authorized capital of $150,000 to take over the Idaho Group, situated at an elevation of 4,800 feet off the north branch of the Marmot river and six miles from tidewater, will proceed with the development of this promising prospect. The par value of the shares is $10 and the owners receive 8,400 of them, the remainder going to the treasury to be sold as funds are required. Some 375 feet of underground work has been done and a two-foot vein has been exposed for 28 feet. Assays of samples taken every five feet have run from $227.39 to $394.86 a ton, the principal value being in silver.

Dale L. Pitt, general manager of the Premier Gold Mining Co., is reported to have been appointed general representative of the Guggenheim interests in British Columbia with headquarters either at Stewart or Prince Rupert. Besides their interests in the Portland Canal district, the Guggenheims are operating at several points along the National Railways System, northern British Columbia.

Slocan. — William W. Buchanan, manager of the Meteor Mine, Slocan City, reports that shipments from this mine will be resumed in about two weeks. It is stated that a body of high-grade ore was uncovered recently.

The judgment given against Clarence Cunningham, a prominent mining operator of the Slocan district, by the lower courts in favor of Robert Insinger, a banker of Spokane, Wn., with reference to the purchase of the Hewitt and Lorna Doone mines, Silverton, has been confirmed by the Supreme Court of Canada. On August 15, 1918, Cunningham agreed to purchase these properties for $175,000. He paid $50,000, instead of half the purchase price as arranged, and was granted an extension of his option to purchase conditional upon undertaking certain tunnelling work. Before the option expired Cunningham notified Insinger that he did not intend to make further payments and the option was cancelled. In the B. C. Supreme Court the plaintiff, Insinger, was awarded an accounting of monies due him under the purchase agreement and damages for the development that should have been done on the extension of the option.

Trail Ore Receipts. — Ore receipts at the Trail smelter, Consolidated Mining and Smelting Co. of Canada, for the period November 22nd to 30th, totalled 9,771 tons. The shipments in detail follow:

	Tons

Iron Bounty to be Renewed.—For some years British Columbia has offered a bounty of $3 a ton on pig iron manufactured in the province from domestic ore and $1.50 a ton on pig iron manufactured in the province from foreign ore. The bounty, as the statute now reads, expires on the 31st of December, 1923. It is understood that legislation is to be introduced extending the period of the offer at the present session of the legislature. It is possible that the provincial government will sponsor further legislation designed for the encouragement of the establishment of an iron and steel industry in the province. Just how far this will go cannot be said, but at least it will be an indication of the desire of the administration to support, as far as it is able financially and in other respects, any private interests, British or American, who may contemplate investment in such an enterprise in British Columbia.

COPPER PLANT CLOSED

Recently the copper smelter at Messina in South Africa, was fitted with apparatus for firing with powdered coal. The coal used is high in ash, and the furnaces were burnt out and now are shut down for repairs. It is possible that on account of the relatively poor quality of the coal available converters may have to be substituted for the present reverbera- tories.

NOVA SCOTIA

New Shaft being Completed. Number 14 shaft Dominion Collieries, Glace Bay, is timbered and completed and temporary cages are being put on to hoist rock from the pit bottom, which is being put into shape for output. As this shaft was not put down on virgin coal but on a section that previously had been worked, although at this point strong pillars had been left to support the long projected shaft, the pit bottom required has been strongly supported and reinforced.

The shaft pillars and roadways in the vicinity of the shaft are lined with concrete from twelve to eighteen inches thick. The roof is supported with 10″ Bethlehem steel H sections. For a short distance on either side of the shaft, the approaches will be twenty-four wide. This section is supported by 18″ steel beams resting on twelve-inch columns and tied with floor beams. The pit bottom is one-third completed and is expected to be ready by May or June of next year.

The main haulage way, which is 9,000 ft. long, is about one-half completed. Roads have been graded, the roof blasted down and pack-walls built a distance of 4,000 feet. Of this, 1,000 feet has been faced with concrete and this work will be carried on to the inner turn-out. As this is to be the first real experiment with electric haulage, everything is being done with the object of safety and permanency. Nothing is being left to chance. Provision has been made for stone-dusting the many haulage ways as a preventive against coal-dust explosions.

There will be two miles of track, 60-lb. rails for electric locomotive haulage, 30-lb. rails will be laid on subsidary haulage ways such as levels and headways and 20-lb. rails in rooms. These are 5 pounds heavier than any other colliery because the pit box will be of greater capacity and will, when loaded, be slightly over three tons.

It was intended at the beginning to put in electric mining machines, but it has now been decided that, for the present, air coal-cutting machines will be continued. Those now in use are the Ingersoll and the Radial. Experiments are being made with the Mavor and Coulson and the Hardy, but the type to be in general use has not been selected.

The mine will be equipped for an output of 2,000 tons, which later on will be increased to 2,500 tons. For a number of years two-thirds of the output will be drawn from rise workings. The main levels will run towards the sea.

Wage Negotiations Progressing Satisfactorily. — A sub-committee composed of representatives of the Executive officers, District No. 26, U. M. W. of A. and Besco colliery officials, with the help of Mr. F. W. Gray, drew up the basis of an agreement, to be put into force provided an understanding is reached on the wage scale. It took a few weeks to put the agreement in shape and to make it clear and cover all the conditions at the collieries; but the committee believe they have got somewhere near to what they aimed at, and look upon it as the first real agreement made since the United Mine Workers of America began to regulate labor affairs in Nova Scotia. The wage discussion will go over until after the holidays, when it will be taken up again with the purpose of being ready by January 15th.

At present there is much idleness at the collieries and it is generally believed that, until a satisfactory agreement is reached, it will continue, as no large coal contracts can be booked until the Company know what the cost of coal is going to be. If the men and the Company are able to get together, Cape Breton will, no doubt, have a good year. There will be no labor interruptions, as these are guarded against in the basis of the agreement. There will be nothing but new local conditions that may arise to deal with, and these also are covered in the contract. Let us hope that by the middle of January the miners of the Province will know that a good year's work is ahead and they have done their own part in bringing it about.

Steel Plant and Collieries Slowing Down. — There is a further slowing up in the steel and coal trade of Nova Scotia and there is much idle time at the collieries. The mines with the best quality of coal are getting the best of the work. This is rather hard on the workmen who find themselves in a district where the coal is of an inferior quality; not that there is much of this inferior coal, but it is not good metallurgical coal and when the outside market for domestic coal is satisfied, the home market cannot take it.

The steel plant, Sydney, is laying off a large number of men. Expected orders have not yet come in and the Company will not stock its products so heavily this year as last. Last winter 35,000 tons of rails were rolled, to give employment, and these were kept on hand for several months. This effort was not appreciated by the workmen, who by their actions added to the cost of production.

The Year's Coal Output. — The Coal output of Nova Scotia for 1923 has been 5,317,000 tons, against 4,457,000 tons in 1922. Every coal-mining county shows an increase. Especially in the latter half of the year the daily outputs were large and indicated the increased capacity of the collieries. An analysis of the first six months' output in Cape Breton county is very interesting, and from an industrial standpoint illuminating, as to the disastrous effect of a coal strike. The total output of the first six months for the Dominion collieries was 1,876,967 tons. Compared with the first six months of the previous year, when "striking on the job" was encouraged, the increase was over 700,000 tons. Compared with the last six months of 1923, after the July strike, when contracts of 400,000 tons had been cancelled because of the strike, the increase was only 393,273 tons, and this at a time when each succeeding month showed very large daily outputs.

Output Capacity, 7,000,000 tons. — The collieries of Nova Scotia are in a position to give an output of 7,000,000 tons in 1924 if trade demands it. With a reasonable agreement signed up between the coal operators and the United Mine Workers (and there are strong grounds for believing this will come), 1924 should, if prices are right, put the coal trade of the Province on its feet. There is much need of a quiet, busy year when both labor and capital will unite to

SALES OF CALCIUM ARSENATE

At a meeting in New York recently of those interested in the arsenic trade, it was disclosed that the consumption of calcium arsenate was doubled during the past season, being about 31,000,000 pounds. It was estimated that, if the price next year were reduced to 11 to 13 cents a pound, the demand would be from 65,000,000 to 75,000,000 pounds, while at 16 cents, the amount sold would be [illegible] to 40,000,000 pounds.

SOME USES OF QUARTZ

In its annual report on the mineral resources of the United States, the Geological Survey gives the following description of the uses of silica:

Miscellaneous Uses of Silica

Silica is used for many purposes, principally in the manufacture of pottery, paints, and scouring soaps, as a wood filler, as a polisher, and in metallurgical and chemical processes. In the pottery industry, where it is generally called flint, silica is used in the body of the ware to diminish shrinkage and is also used in glazes. Silica for use in pottery should contain less than 0.5 per cent of iron-bearing minerals. Manufacturers of paint use considerable quantities of very finely ground silica, which forms as much as one-third of the total pigment in some paints. For this purpose finely ground crystalline material is superior to fine sand in its natural state because of the angularity of the grains, which makes them adhere more firmly to the article painted and after wear affords a good surface for repainting. The same angularity makes artificially comminuted crystalline quartz superior to natural sand for use in wood fillers. For soaps and polishing powders ground material is preferred to natural sand on account of its whiteness and angularity. For all these purposes large quantities of pure quartz sand and sandstone are finely ground and yield a product fully equal to that obtained by grinding massive crystalline quartz.

Quartz crushed and graded to various sizes is used in making sandpaper and sand belts, as a scouring agent, for "frosting" glass with sand-blast apparatus, and for other purposes. Blocks of massive quartz and quartzite are used in the chemical industry as a filler for acid towers and as a flux in copper smelting. Ground quartz is also used in filters and in tooth powders and by dentists as a detergent.

The material known commercially in the United States as tripoli, which is the siliceous residue of decomposed limestone, also yields an excellent grade of pulverized silica, which is used for the same purpose as silica powder obtained from massive crystalline quartz and from sand and sandstone. Diatomaceous (infusorial) earth is also used to make polishing powder that is employed for similar uses to those for which quartz, sand, and tripoli powders are employed, but diatomaceous earth has somewhat different properties, and most of it finds different application, as insulating and filter material.

Sand and crystalline quartz have been used in making silicon and alloys of silicon with iron, copper, and other metals in the electric furnace. Quartz may be fused in the electric furnace to make chemical apparatus, such as tubes, crucibles, and dishes.

Quartz Glass

The making of quartz glass received its impetus from several directions. Chemists needed glassware, especially in the form of tubes that were more resistant to chemical reagents and to heat than any glasses of more complex composition. Mercury arc lamps, now largely used for water sterilization, require a tube that will stand a temperature in the neighborhood of 600 deg. C. The application of ultra-violet rays also demands clear glass rods and tubes, and chemical manufacturers need large tubing that is resistant to heat and to corrosion by hot gases and vapors. For some chemical work glasses do not need to be clear, but the glass used in mercury arc lamps must be transparent. Most quartz contains bubbles of air, water, carbon dioxide, or other substances which, on heating, become greatly enlarged, and when molten the quartz may appear satiny from the great number of bubbles, which were almost unnoticeable before. For those uses in which it is not necessary to have a transparent glass, a pure quartz sand furnishes a good raw material, but for transparent glass only the purest quartz in large pieces can be used, so that the difference in the price of glass free from bubbles and that containing only comparatively few bubbles may appear disproportionately large. Another reason for the greater cost of the transparent glass is the great loss through volatilization of melted quartz. A charge of 5 or 6 pounds of quartz is melted in less than 20 minutes in an electric furnace, but in that time it loses 20 per cent by volatilization. If the charge is sand or some other cheap grade of quartz, such a loss means little, but with a charge of high-grade Brazilian pebble the loss is more serious.

The first quartz glass was all formed by hand, and handwork is still used for crucibles, breakers, and similar ware. Tubing and rods, however, are now made mechanically of various sizes and lengths. An extremely clear glass is made by the General Electric Co. at Lynn, Mass., where Dr. E. R. Berry has conducted experiments for the last seven years and where a large quartz-glass plant was to be constructed during 1923. The quartz used for the glass is the best Brazilian pebble, carefully treated with acids so as to remove all traces of iron and other soluble materials. Dr. Berry has so far solved his problem that he is able to make mechanically tubes and rods of definite sizes.

Difficulties of Manufacture

One of the greatest inducements for the working out of mechanical methods of quartz-glass manufacture has been the difficulty in developing and handling skilled workmen in quartz glass. When heated to the melting point quartz glass is so incandescent that the light it gives is too dazzling to allow the glass to be worked by direct vision, so that in general it is worked by men wearing dark spectacles, and between them and the work is a dark plate glass plate. Little of the work that is not incandescent can be seen through the spectacles, and as only small parts of the glass can be kept heated in the small oxy-acetylene flames used and it is necessary to examine the glass more closely at frequent intervals, the spectacles must be removed and the work allowed to cool. These difficulties make the work extremely trying and introduce complications in directing such labor.

In making tubes for mercury arc lamps it is necessary that the tubes be welded with glass that can be worked at lower temperatures, and this is accomplished by making a mixture of quartz and "pyrex" glass, which changes regularly from pure quartz to pure "pyrex." Quartz-glass tubing is now made in diameters reaching several inches and in complex coils, for the condensation of acids and other hot fumes.

Uses of Quartz-Glass

In the mechanical making of clear-glass tubes and rods very heavy gas pressures are sometimes used, and the rods and tubes are extruded directly into water. The resistance of quartz glass to extreme changes in temperature is one of its most valuable qualities. Rods and tubes 26 feet long have been made by the General Electric Co., and the rods are so transparent that when a burning match is held at one end the light emerges at the other end apparently almost undiminished. Its remarkable transparency, its hardness, and its high index of refraction make quartz glass a very desirable material for lenses, and Dr. Berry hopes to be able to obtain it free enough from bubbles to make telescope lenses.

Quartz glass is useful in ultra-violet ray work because it is transparent to the rays, whereas ordinary glasses are opaque. This property of quartz glass has been utilized in making mercury arc lamps for the sterilization of water supplies and for the treatment of disease. Swimming pools in which it is not easy to change the water are equipped with one or more of the arc lamps, depending on the number of bathers and the size of the pool. The lamps are placed in a trough through which the water is constantly pumped. It is said that two lamps will thoroughly sterilize and keep sterile water in a pool in which several hundred persons are bathing. One pool on the East Side in New York in which two lamps were operated and in which the water was not changed during an entire season is said to have shown less live germs at the end of the time than the water contained when it was drawn from the city mains.

Ultra-violet rays are used in the treatment of wounds and diseases of the jaws and nasal passages. Two forms of apparatus have been used. In one form the rays were applied through a hollow cone of quartz glass having most of its surface covered with a metallic film, leaving only the point through which the rays passed. It is difficult to apply such an apparatus to the inside of the mouth, and therefore another form has been devised in which solid rods of transparent quartz glass are attached directly to a small water-cooled mercury are that is easily held in the hand, and the rods are bent to suit the portion of the mouth to which the rays are to be applied. The rays will follow the rod, as a fluid follows a tube, and leave the rod at the end.

USES OF BARITE

Barite is used as a finely ground powder in combination with zinc as lithopone, and to make as miscellaneous barium compounds.

Barytes is ground to very fine powder, leached with acid, and washed for use as a pigment, a filler, and an inert base. Most barytes is refined by flotation on a stream of water, whereby only the most impalpable powder is obtained. As a pigment it is used chiefly in interior flat white or light-colored paints. As a filler it is extensively used in rubber goods, linoleum, oilcloth, highly glazed paper, and similar white glazed articles. It forms an inert base on which dyes are precipitated to make lakes or colored paints. Ground barytes has also been used in making brick for the construction of X-ray laboratories, in place of a lining of sheet lead, to prevent the rays from escaping and doing possible injury.

Lithopone is a pigment prepared chemically from barytes and zinc. It is an intimate mixture of chemical precipitates of barium sulphate and zinc sulphide in the proportion of about 70 per cent. sulphate and 30 per cent. sulphide. It is of exceedingly fine grain and is used not only in paint but as a filler in rubber goods, linoleum, oilcloth, window shades and certain kinds of paper.
